Hoos / Stützle

Stochastic Search Algorithms

Motivation: Why Stochastic Search?

Stochastic search is the method of choice for solving many hard combinatorial problems.

Recent Progress & Successes:

- Ability of solving hard combinatorial problems has increased significantly
 - Solution of large propositional satisfiability problems
 - Solution of large travelling salesman problems
- Good results in new application areas

Reasons & Driving Forces:

- New algorithmic ideas
 - Nature inspired algorithms
 - New randomisation schemes
 - Hybrid and mixed search strategies
- Increased flexibility and robustness
- Improved understanding of algorithmic behaviour
- Sophisticated data structures
- Significantly improved hardware

Hoos / Stützle

Stochastic Search Algorithms

Goals of the Tutorial

Provide answers to these questions:

- What is stochastic search and how can it be used to solve computationally hard problems?
- Which stochastic search techniques are available and what are their features?
- How should stochastic search algorithms be studied and analysed empirically?
- How are specific problems solved using stochastic search?

Outline

Introduction

Part I: Combinatorial Problems and Search

- Combinatorial problems
- Complexity issues
- Search methods
- Stochastic search

[Short Break]

Hoos / Stützle

Stochastic Search Algorithms

Part II: Stochastic Local Search Methods

- Simulated Annealing
- Tabu Search
- Iterated Local Search
- Evolutionary Algorithms
- Ant Colony Optimization

[Short Break]

Part III: Stochastic Search Behaviour

- Empirical evaluation
- Search space characteristics
- Parameterisation and tuning

[Short Break]

Hoos / Stützle

Stochastic Search Algorithms

Part IV: Applications

- SAT
- Traveling Salesman Problem
- Quadratic Assignment Problem
- Scheduling
- Planning
- Combinatorial Auctions

Conclusions and Issues for Future Research

Part I

Combinatorial Problems and Search

Hoos / Stützle

Stochastic Search Algorithms

Combinatorial Problems

Examples for combinatorial problems:

- finding shortest/cheapest round trips (TSP)
- finding models of propositional formulae (SAT)
- planning, scheduling, time-tabling
- resource allocation
- protein structure prediction
- sequencing genomes

Combinatorial problems ...

- typically involve finding a grouping, ordering, or assignment of a discrete set of objects which satisfies certain constraints
- arise in many domains of computer science and various application areas
- have high computational complexity (\mathcal{NP} -hard)
- are solved in practice by searching an exponentially large space of candidate / partial solutions

Hoos / Stützle

Stochastic Search Algorithms

Combinatorial Decision Problems:

For a given problem instance, decide whether a solution (grouping, ordering, or assignment) exists which satisfies the given constraints.

The Propositional Satisfiability Problem (SAT)

Simple SAT instance (in CNF):

 $(a \lor b) \land (\neg a \lor \neg b)$

 \rightsquigarrow satisfiable, two models:

a =true, b =false a =false, b =true

Hoos / Stützle

Stochastic Search Algorithms

13

SAT Problem – decision variant:

For a given propositional formula Φ , decide whether Φ has at least one model.

SAT Problem – search variant:

For a given propositional formula Φ , if Φ is satisfiable, find a model, otherwise declare Φ unsatisfiable.

SAT ...

- is a pervasive problem in computer science (Theory, AI, Hardware, ...)
- is computationally hard (\mathcal{NP} hard)
- can encode many other combinatorial problems
 (*NP* completeness)
- is one of the conceptually simplest combinatorial decision problems

 \rightsquigarrow facilitates development and evaluation of algorithmic ideas

Hoos / Stützle

Stochastic Search Algorithms

Combinatorial Optimisation Problems:

Objective function (evaluation function) assigns a numerical value to each candidate solution.

For a given problem instance, find a solution (grouping, ordering, or assignment) with maximal (or minimal) value of the evaluation function.

The Traveling Salesperson Problem (TSP)

TSP – optimisation variant:

For a given weighted graph G = (V, E, w), find a Hamiltonian cycle in G with minimal weight, i.e., find the shortest round-trip visiting each vertex exactly once.

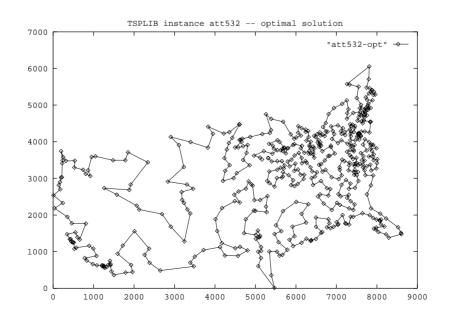

TSP – decision variant:

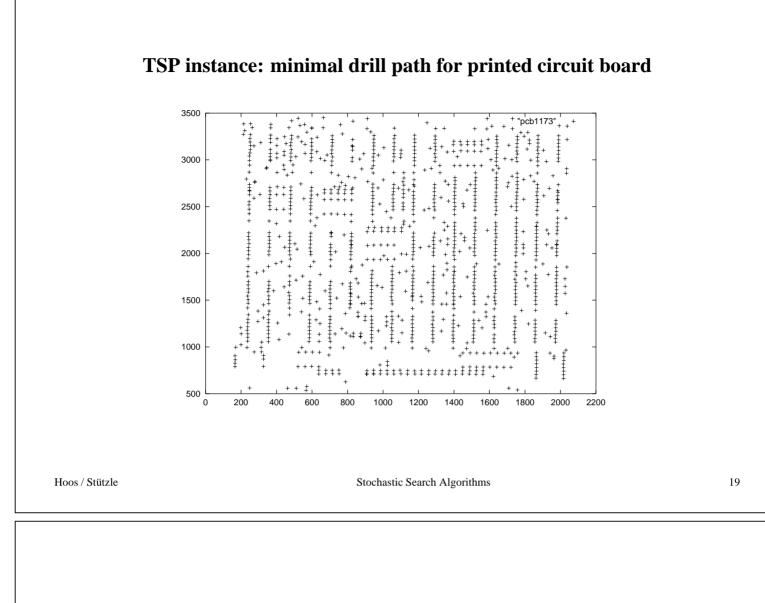

For a given weighted graph G = (V, E, w), decide whether a Hamiltonian cycle with minimal weight $\leq b$ exists in G.

Hoos / Stützle

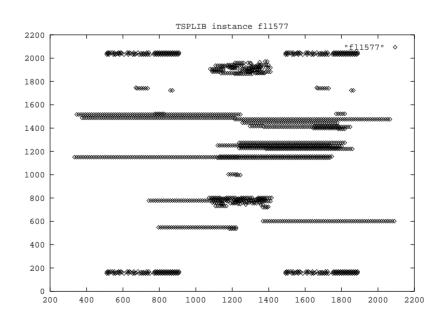

Stochastic Search Algorithms

TSP instance: shortest round trip through 532 US cities

TSP instance: minimal drill path for printed circuit board

TSP ...

- is one of the most prominent and widely studied combinatorial optimisation problems in computer science and operations research
- is computationally hard (\mathcal{NP} -hard)
- is one of the conceptually simplest combinatorial optimisation problems

 \rightsquigarrow facilitates development and evaluation of algorithmic ideas

Hoos / Stützle

Stochastic Search Algorithms

Generalisations of combinatorial problems:

- many combinatorial decision problems naturally generalise to optimisation problems, e.g. SAT to MAX-SAT
- many combinatorial problems have practically relevant dynamic variants (dynamic SAT, dynamic TSP, internet routing, dynamic scheduling)
- often, algorithms for decision problems can be generalised to optimisation and / or dynamic variants
- typically, good solutions to generalised problems require additional heuristics.

Complexity Issues

Motivation:

Analyse inherent hardness of problems and inherent complexity of algorithms

Some basic concepts and results:

- complexity classes: \mathcal{P} vs. \mathcal{NP}
- \mathcal{NP} -completeness, \mathcal{NP} -hardness
- $\mathcal{P} \neq \mathcal{NP}$ not known
- *but:* if there were an efficient (polynomial) algorithm for any *NP*-complete problem, all *NP* problems could be solved efficiently

Hoos / Stützle

Stochastic Search Algorithms

Complexity of combinatorial decision problems:

- many combinatorial decision problems are \mathcal{NP} -hard
- this is reflected in search spaces of size exponential in problem size
- SAT is *the* classical example of an \mathcal{NP} -complete problem
- TSP (decision variant) is \mathcal{NP} -complete
- *but:* not all combinatorial problems with large search spaces are hard (2 SAT / Horn SAT, shortest path, minimal spanning tree.)

Complexity of combinatorial optimisation problems:

- complexity of optimisation vs. decision variants
- approximation algorithms
- approximability / inapproximability

Some results for the TSP:

- general TSP: inapproximable for arbitrary constant bounds on solution quality
- TSP with triangle inequality: polynomially approximable to 1.5. optimal solution
- Euclidean TSP: polynomial approximation schema exists

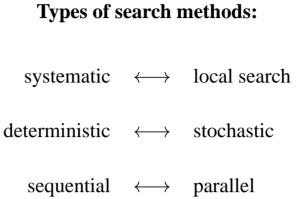

Hoos / Stützle

Stochastic Search Algorithms

Are computationally hard problems really intractable?

- \mathcal{NP} -hardness results apply to the worst case but do not imply that all instances of a problem are hard to solve
- approximate solutions are often useful and easier to compute
- heuristics can often help to solve practically important classes of instances in reasonable time
- randomisation can help to find good solutions reasonably efficient with high probability
- parallelisation can help to increase size of practically soluble instances

Search Methods

Hoos / Stützle

Stochastic Search Algorithms

Properties of search methods:

Decision problems: *complete* vs. *incomplete*

Optimisation problems: *exact* vs. *approximate*

'Classical' search algorithms based on back-tracking:

- iteratively construct candidate solution
- use back-tracking to explore full search space
- use appropriate techniques for pruning search space

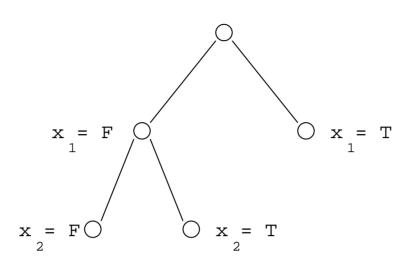

Hoos / Stützle

Stochastic Search Algorithms

The 'Davis-Putnam' algorithm for SAT

- iteratively select variables and search both truth assignments for these
- backtracking guarantees completeness of search
- use unit propagation to prune search space
- ordering of variables and values is critical for performance

Binary search tree for Davis-Putnam-style algorithm

Hoos / Stützle

Stochastic Search Algorithms

31

Branch-and-bound methods for the TSP

- extension of backtracking algorithms which additionally considers solution cost
- branching partitions the set of solutions represented at current node in exclusive sets
- lower bound estimates completion cost of partial solutions
- upper bound estimates the optimal solution from above
- partial solutions are discarded if lower bound is larger than upper bound
- analogous to A^* search in AI

Local Search (LS) Algorithms

search space S

(SAT: set of all complete truth assignments to propositional variables)

solution set $S' \subseteq S$

(SAT: models of given formula)

neighbourhood relation $\mathcal{N} \subseteq S \times S$

(SAT: neighbouring variable assignments differ in the truth value of exactly one variable)

objective function $f: S \mapsto \mathbb{R}^+_0$

(SAT: number of clauses unsatisfied under given assignment)

Hoos / Stützle

Stochastic Search Algorithms

33

Local Search:

- start from initial position
- iteratively move from current position to neighbouring position
- uses objective function for guidance

Two main classes

- local search on partial solutions
- local search on complete solutions

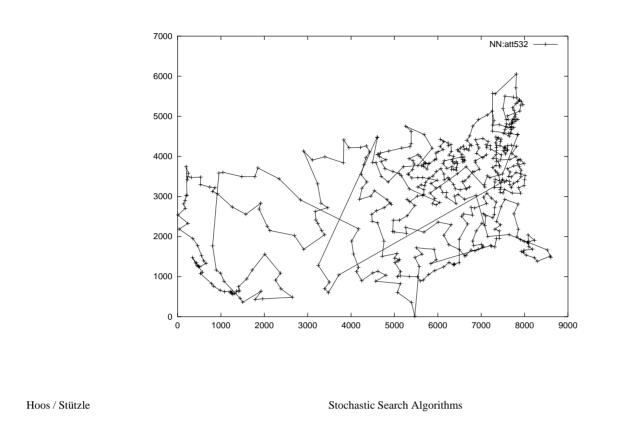

Construction Heuristics:

- specific class of LS algorithms
- search space: space of partial solutions
- search steps: extend partial solutions, but never reduce them
- Neighbourhood typically given by individual solution elements
- solution elements are often ranked according to a greedy objective function

Stochastic Search Algorithms

Nearest Neighbor heuristic for the TSP:

- always choose at the current city the closest unvisited city
 - choose an arbitrary initial city $\pi(1)$
 - at the *i*th step choose city $\pi(i+1)$ to be the city *j* that minimises $\{d(\pi(i), j)\}; j \neq \pi(k), 1 \leq k \leq i$
- running time $\mathcal{O}(n^2)$
- worst case performance $NN(x)/OPT(x) \le 0.5(\lceil \log_2 n \rceil + 1)$
- other construction heuristics for TSP are available

Nearest neighbour tour through 532 US cities

Example of a (greedy) construction heuristic for SAT

- start with empty variable assignment
- in each step select an unassigned variable and set it to a truth value
 - if ∃ unsatisfied clause with only one unassigned variable, assign this variable to satisfy this clause
 - otherwise choose variable and truth value such that maximal number of clauses become satisfied

Construction Heuristics ...

- can be used iteratively to solve combinatorial problems
- provide only a limited number of different solutions
- can be combined with back-tracking to yield systematic search algorithms (e.g., Davis-Putnam for SAT)
- are used within some state-of-the-art local search approaches (e.g., Ant Colony Optimisation)

Stochastic Search Algorithms

Local Search on complete solutions

- widely used class of LS algorithms
- search space: the space of feasible solutions (SAT: complete truth assignments, TSP: valid round trips)
- initial position often randomly chosen
- search steps: move from current solution to neighbouring, feasible solutions

Iterative Improvement (Greedy Search):

- initialise search at some point of search space
- in each step, move from the current search position to a neighbouring position with better objective function value

Hoos / Stützle

Stochastic Search Algorithms

41

procedure BestImprovementStep($s \in S$) $w = \emptyset, s^* = s$ while $(\mathcal{N}(s)/w \neq \emptyset)$ do s' = GenerateSolution(s) $w = w \cup s'$ if $(f(s') < f(s^*))$ $s^* = s'$ end return s^* end BestImprovement

Iterative Improvement for SAT

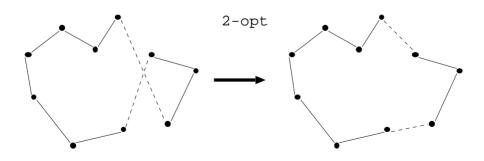

- initialisation: randomly chosen, complete truth assignment
- neighbourhood: variable assignments are neighbours iff they differ in truth value of one variable
- objective function: number of clauses unsatisfied under given assignment

Hoos / Stützle

Stochastic Search Algorithms

Iterative Improvement for the TSP

- initial solution is a complete tour
- k-opt neighbourhood: solutions which differ by at most k edges

- neighborhood size $\mathcal{O}(n^k)$
- More complex neighbourhoods: variable depth search

Stochastic Local Search

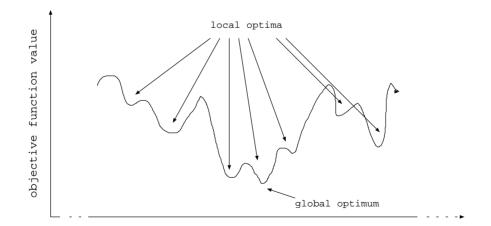

Typical problems with local search:

- getting stuck in local optima
- being misguided by objective function

Hoos / Stützle

Stochastic Search Algorithms

45

solution space

Stochastic Local Search:

- randomise initialisation step
 - random initial solutions
 - randomised construction heuristics
- randomise search steps such that suboptimal/worsening steps are allowed ∼→ improved performance & robustness
- typically, degree of randomisation controlled by noise parameter
- allows to invest arbitrary computation times

Hoos / Stützle

Stochastic Search Algorithms

47

Pros:

- for many combinatorial problems more efficient than systematic search
- easy to implement
- easy to parallelise

Cons:

- often incomplete (no guarantees for finding existing solutions)
- highly stochastic behaviour
- often difficult to analyse theoretically / empirically

Simple SLS methods

Random Search (Blind Guessing):

In each step, randomly select one element of the search space.

(Uninformed) Random Walk:

In each step, randomly select one of the neighbouring positions of the search space and move there.

Hoos / Stützle

Stochastic Search Algorithms

49

Randomised Iterative Improvement:

- initialise search at some point of search space
- search steps:
 - with probability p, move from current search position to a randomly selected neighbouring position
 - otherwise, move from current search position
 to neighbouring position with better objective function value

Randomised Systematic Search

Typical problems with systematic search:

- abysmal performance for certain instances
- being misguided by search heuristic

Hoos / Stützle

Stochastic Search Algorithms

51

Randomised Systematic Search:

- degree of randomisation controlled by noise parameter
- additionally, use random restart

Randomised Davis-Putnam algorithm for SAT

- randomise selection of variable to be instantiated next and/or order of instantiations (with truth values)
- algorithm remains complete

 → increased robustness and performance when combined with random restart strategy and using tuned parameter settings (e.g., satz-rand [Gomes et al.])

Stochastic Search Algorithms

Pros:

- increased robustness, in particular when using suitably tuned noise and restart strategies
- simple, generic extension of systematic search
- resulting algorithms typically still complete
- potential for easy parallelisation

Cons:

- highly stochastic behaviour
- difficult to analyse theoretically / empirically
- parameter tuning often difficult, but critical for obtaining good performance

Part II

Stochastic Local Search Methods

Hoos / Stützle

Stochastic Search Algorithms

Overview:

- Parameterised local search extensions
 - Simulated Annealing
 - Tabu Search
- hybrid strategies
 - Iterated Local Search
 - Evolutionary Algorithms
 - Ant Colony Optimization
 - → representation as Generalized Local Search Machines (GLSMs)

These SLS algorithms are general frameworks for the design of heuristic algorithms and are often called *metaheuristics*.

Metaheuristic: general-purpose heuristic method designed to guide underlying problem specific heuristic (e.g., local search algorithm or construction heuristic) towards promising regions of the search space.

Hoos / Stützle

Stochastic Search Algorithms

Simulated Annealing

Combinatorial search technique inspired by the physical process of annealing [Kirkpatrick et al. 1983, Cerny 1985]

- physical annealing process:
 - 1. heat up a solid until it melds
 - 2. decrease slowly the temperature to reach a ground state
- algorithmic analogy:

states \leftrightarrow solutions

energy $\leftrightarrow \rightarrow$ objective function

Simulated Annealing – general outline

- generate a neighboured solution / state
- probabilistically accept the solution / state probability of acceptance depends on the objective function (energy function) difference and an additional parameter called temperature

Stochastic Search Algorithms

Solution generation

• typically returns a random, neighboured solution

Acceptance criterion

- Metropolis acceptance criterion
 - better solutions are always accepted
 - worse solutions are accepted with probability

$$\sim \exp\left(\frac{f(s) - f(s')}{T}\right)$$

Annealing

• parameter T, called temperature, is slowly decreased

Generic choices for annealing schedule

- initial temperature T₀
 (example: based on statistics of objective function)
- temperature function how to change temperature (example: geometric cooling, $T_{n+1} = \alpha \cdot T_n, n = 0, 1, ...$)
- number of iterations at each temperature (example: multiple of the neighbourhood size)
- stopping criterion (example: no improved solution found for a number of temperatures)

Hoos / Stützle

Stochastic Search Algorithms

Example application to the TSP [Johnson & McGeoch, 1997]

- baseline implementation
 - start with random initial solution
 - uses 2-opt neighborhood
 - straightforward annealing schedule
 - \rightsquigarrow relatively poor performance
- improvements
 - look-up table for acceptance probabilities
 - neighbourhood pruning
 - low-temperature starts

Discussion

- SA is historically important
- easy to implement
- convergence proofs: theoretically interesting, but practical relevance very limited
- good performance often at the cost of substantial run-times

Hoos / Stützle

Stochastic Search Algorithms

63

Tabu Search

Combinatorial search technique which heavily relies on the use of an explizit memory of the search process [Glover 1989, 1990]

- systematic use of memory to guide search process
- memory typically contains only specific attributes of previously seen solutions
- simple tabu search strategies exploit only short term memory
- more complex tabu search strategies exploit long term memory

Simple tabu search algorithm – exploiting short term memory

- in each step move to best neighboured solution although it may be worse than current one
- to avoid cycles, tabu search tries to avoid revisiting previously seen solutions
- avoid storing complete solutions by basing the memory on solution attributes of recently seen solutions
- tabu solution attributes are often defined via local search moves
- a tabu list stores attributes of the *tl* most recently visited solutions; parameter *tl* is called *tabu list length* or *tabu tenure*
- solutions which contain tabu attributes are forbidden

Hoos / Stützle

Stochastic Search Algorithms

- problem: previously unseen solutions may be tabu
 → use of *aspiration criteria* to overwrite tabu status
- stopping criteria:
 - all neighbored solutions are tabu
 - maximum number of iterations
 - no. of iterations without improvement
- appropriate choice of tabu tenure critical for performance

 → robust tabu search [Taillard, 1991], reactive tabu search [Battiti, Tecchiolli, 1994–1997]

Example: Tabu Search for SAT / MAX-SAT [Hansen & Jaumard, 1990; Selman & Kautz, 1994]

Neighborhood: assignments which differ in exactly one variable instantiation

Tabu attributes: variables

Tabu criterion: flipping a variable is forbidden for a given number of iterations

Aspiration criterion: if flipping a tabu variable leads to a better solution, the variable's tabu status is overwritten

Hoos / Stützle

Stochastic Search Algorithms

67

Tabu search — use of long term memory

Longer term memory: often based on some measure of frequency, e.g., the frequency of local search moves

Intensification strategies: intensify the search in specific regions of the search space

- recover *elite* solutions and restart search around such solutions
- lock some solution attributes, e.g., in the TSP edges contained in several elite solutions may be locked

• . . .

Diversification Strategies: drive the search towards previously unexplored search space regions

- introduce solution attributes which are not very frequently used, e.g., by penalizing frequently used solution attributes
- Restarting mechanisms which bias construction heuristics
- . . .

Hoos / Stützle

Stochastic Search Algorithms

Discussion

- short term memory strategies alone often perform astonishingly well
- additional intensification and diversification strategies can considerably improve performance
- several additional strategies available (e.g., strategic oscillation, path relinking, ejection chains, ...)
- rather complex to use
- very good performance but often at the cost of time-intensive fine-tuning

Hybrid stochastic search techniques

Note: Many of the best-performing SLS algorithms are *combinations* of various simple search strategies.

E.g.: greedy hillclimbing + Random Walk, Ant Colony Optimisation + 3-opt, ...

 \rightsquigarrow conceptual separation of simple search strategies and (higher-level) search control.

Hoos / Stützle

Stochastic Search Algorithms

GLSMs – Generalised Local Search Machines

- search control = non-deterministic finite state machine
- simple search strategies = states
- change of search strategy = transitions between states

State transition types:

- deterministic: DET
- unconditional probabilistic: PROB(*p*)
- conditional probabilistic: CPROB(*C*,*p*)

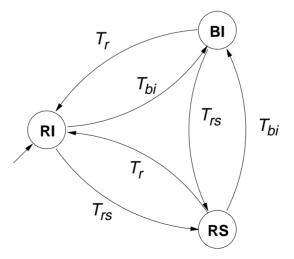

- allows adequate and uniform represention of local search algorithms
- facilitates design, implementation, and analysis of hybrid algorithms
- provides the conceptual basis for some of the best known SLS algorithms for various domains (e.g., SAT [Hoos 1999])

Hoos / Stützle

Stochastic Search Algorithms

GLSM representation of Randomised Best Improvement

Iterated Local Search (ILS)

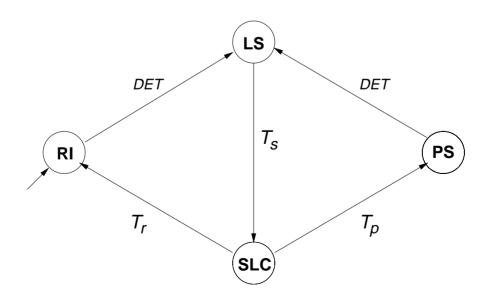

Iterative application of local search to modifications of previously visited local minima

- basic idea: Build a chain of local minima
- the search space is reduced to the space of local minima
- simple, but powerful way to improve local search algorithms

Hoos / Stützle

Stochastic Search Algorithms

Why is ILS a good idea?

- speed large number of local search applications in given time
- bias towards good solutions
- very easy to implement
- few parameters

Hoos / Stützle

Stochastic Search Algorithms

Issues for Iterated Local Search applications

- choice of initial solution
- choice of solution modification
 - Too strong: close to random restart
 - Too weak: Not enough to escape from local minima
- choice of local search
 - effectiveness versus speed
- choice of acceptance criterion
 - strength of bias towards best found solutions

ILS for the TSP

- local search: 2-opt, 3-opt, Lin-Kernighan
- solution modification: non-sequential 4-opt move (double-bridge move)
- acceptance criterion: apply solution modification to best solution since start of the algorithm; other acceptance criteria may perform better for long run times.

Results

• ILS is among the best available algorithms for the TSP

Hoos / Stützle

Stochastic Search Algorithms

79

Other applications:

- Graph partitioning
- Quadratic Assignment Problem
- Scheduling problems

Related idea:

• Variable Neighbourhood Search

Evolutionary Algorithms

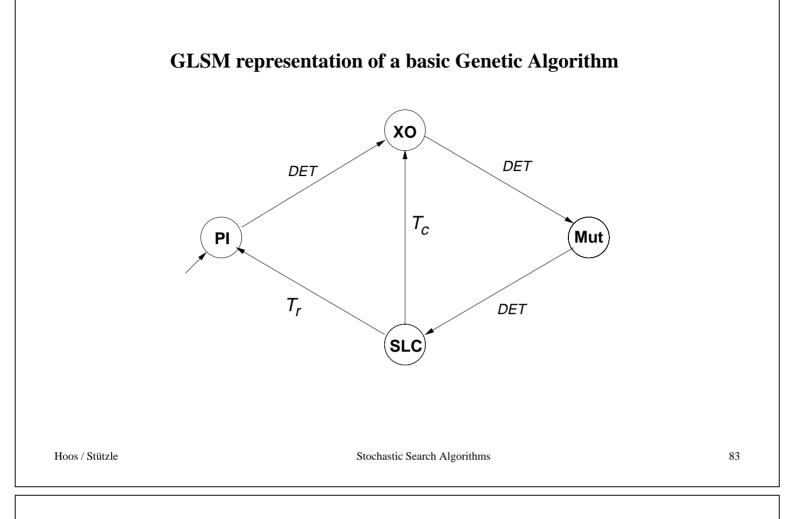

Combinatorial search technique inspired by the evolution of species

- population of strings which are manipulated via evolutionary operators and compete for survival
- population is manipulated via evolutionary operators
 - mutation
 - crossover
 - selection

Hoos / Stützle

Stochastic Search Algorithms

- several variants have been developed
 - Genetic algorithms [Holland, 1975, Goldberg 1989]
 - Evolution strategies [Rechenberg, 1973, Schwefel, 1981]
 - Evolutionary Programming [Fogel, Owens, Walsh, 1966]
 - Genetic Programming [Koza, 1992]
- for combinatorial optimization the most widely used and most effective variant are genetic algorithms

Important issues for evolutionary algorithms

• solution representation

- binary vs. problem specific representation

- fitness evaluation of solutions
 - often defined by objective function of the problem
- crossover operator
 - parent selection scheme
 - problem specific vs. general purpose crossover
 - how can meaningful information be given to the offspring
- mutation operator
 - background operator vs. thriving the search

- selection scheme
 - prefer better solutions for survival
 - elitist strategies
 - maintenance of population diversity
- local search
 - often local search is useful to improve solutions
 - population based search in the space of local optima
 → memetic algorithms
- stopping criteria
 - fixed no. of generations
 - convergence of population

Hoos / Stützle

Stochastic Search Algorithms

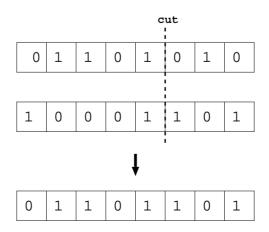

85

GA application to SAT

solution representation: a binary string

evaluation function: no. of violated clauses

crossover operator:

mutation: with a fixed probability flip a variable's truth value

selection: choose best p strings for the next population avoiding duplicate solutions

additional local search: after each crossover or mutation apply a 1-opt local search

Hoos / Stützle

Stochastic Search Algorithms

87

Discussion

- population provides an easy way to increase search space exploration
- large number of different implementation choices
- best performance achieved when operators take problem characteristics into account
- good results for a wide variety of applications

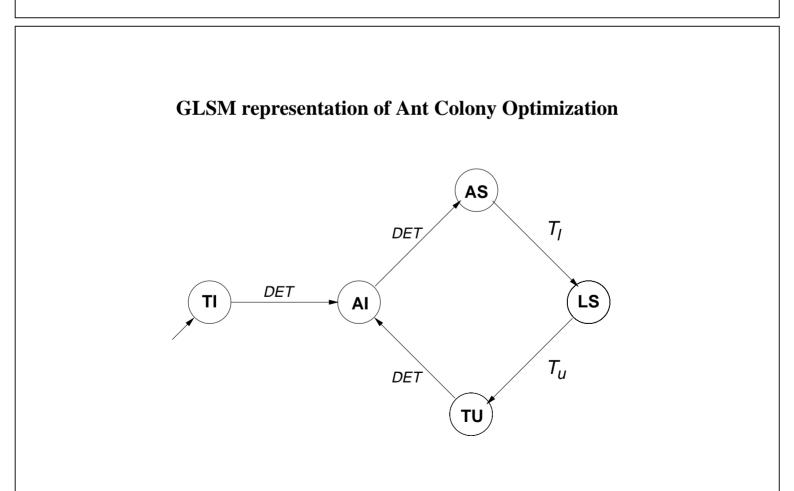

Ant Colony Optimisation

Combinatorial search technique inspired by the foraging behaviour of real ants: [Dorigo et al. 1991, 1996]

- population of simple agents ("ants") communicates indirectly via "pheromone trails" (odorous substance)
- ants follow a local stochastic policy to construct solutions.
- the solution construction is probabilistically biased by pheromone trail information, heuristic information, and the partial solution of each ant
- Pheromone trails are modified during the algorithm's execution to reflect the search experience

Hoos /	Stützle

Stochastic Search Algorithms

Application principles:

- Define *solution components* for the problem to be solved
- Ants construct solutions by iteratively adding solution components
- Possibly improve solutions by applying local search
- Reinforce solution components of better solutions more strongly

Hoos / Stützle

Stochastic Search Algorithms

91

ACO for the TSP – tour construction

- Solution components are "arcs"
- $\eta_{ij} = 1/d_{ij}$: Heuristic information, indicates the utility of going from node *i* to node *j*
- τ_{ij}(t): Intensity of the pheromone trail in iteration t on arc (i, j)
- Probabilistic selection of the next node according to:

 $p_{ij}(t) \sim (\tau_{ij}(t))^{\alpha} \cdot (\eta_{ij})^{\beta}$ if node j allowed

ACO for the TSP – Update of pheromone trails

- Parameter $0 < \rho < 1$, 1ρ represents pheromone evaporation
- Update of the pheromone trails according to (Ant System):

$$\tau_{ij}(t) = \rho \cdot \tau_{ij}(t-1) + \sum_{k=1}^{m} \Delta \tau_{ij}^{k}$$

 Δτ^k_{ij} = 1/L_k if arc (i, j) is used by ant k on its tour L_k: Tour length of ant k m: Number of ants

Several improved extensions have been proposed.

Hoos / Stützle

Stochastic Search Algorithms

93

Discussion

- General framework for ACO applications: ACO Metaheuristic [Dorigo, Di Caro 1999, Dorigo, Di Caro, Gambardella, 1999]
- Two main application fields:
 static problems ←→ dynamic problems
- considerable success despite being a very recent metaheuristic

Characteristics of Various Metaheuristics

Feature	SA	TS	ILS	GA	ACO
Trajectory	+	+			_
Population	_	_	_	+	+
Memory	_	+	Э	Ξ	Э
Multiple neighborhoods	_	—	+	Ξ	—
Sol. construction	_	_		_	+
Nature-inspired	+	_	_	+	+

+: feature present, \exists : partially present, -: not present

Hoos / Stützle

Stochastic Search Algorithms

95

Chance vs. Necessity

- randomisation of search algorithms often increases their performance and robustness
- stochastic search algorithms need to balance randomised and goal-directed search (exploration vs. exploitation, diversification vs. intensification)
- best performance will be achieved if good, problem specific balance is found
- different techniques can be used to achieve this balance
- peak performance obtained by successful exploitation of problem and algorithm specific knowledge
- this knowledge is often still poorly understood

Part III

Analysing and Characterising Stochastic Search Behaviour

Hoos / Stützle

Stochastic Search Algorithms

Analysing Stochastic Search Behaviour

Many SLS algorithms ...

- perform well in practice
- are incomplete, i.e., cannot be guaranteed to find (optimal) solutions
- are hard to analyse theoretically

 \rightsquigarrow empirical methods are used to analyse and characterise their behaviour.

Aspects of stochastic search performance:

- variability due to randomisation
- robustness w.r.t. parameter settings
- robustness across different instance types
- scaling with problem size

Hoos / Stützle

Stochastic Search Algorithms

99

Insights into algorithmic performance...

- help assessing suitability for applications
- provide basis for comparing algorithms
- characterise algorithm behaviour
- facilitate improvements of algorithms

RTD-based empirical methodology:

- run algorithm multiple times on given problem instance(s)
- estimate empirical run-time distributions (RTDs)
- get simple descriptive statistics (mean, stddev, percentiles, ...) from RTD data
- approximate empirical RTDs with known distribution functions
- check statistical significance using goodness-of-fit test

[Hoos & Stützle 1998]

tries

600

700

800

900

This methodology facilitates ...

- precise characterisations of run-time behaviour
- prognoses for arbitrary cutoff times
- empirical analysis of asymptotic behaviour
- fair and accurate comparison of algorithms
- cleanly seperating different sources of randomness (SLS algorithm / random generation of problem instances)

Asymptotic run-time behaviour of SLS algorithms

• complete

— for each problem instance P there is a time bound $t_{max}(P)$ for the time required to find a solution

- probabilistic approximate completeness (PAC property)

 for each soluble problem instance a solution is found with probability → 1 as run-time → ∞.
- essential incompleteness

— for some soluble problem instances, the probability for finding a solution is strictly smaller 1 for run-time $\rightarrow \infty$.

Hoos / Stützle

Stochastic Search Algorithms

Some results [Hoos 1999]:

- Until recently, some of the most prominent and best-performing SLS algorithms for SAT were essentially incomplete
- In practice, essential incompleteness often causes stagnation behaviour which drastically affects the performance of the algorithm
- By a simple and generic modification, (Random Walk Extension) these algorithms can be made PAC in a robust manner.
- The algorithms thus obtained are among the best-performing SAT algorithms known to date.

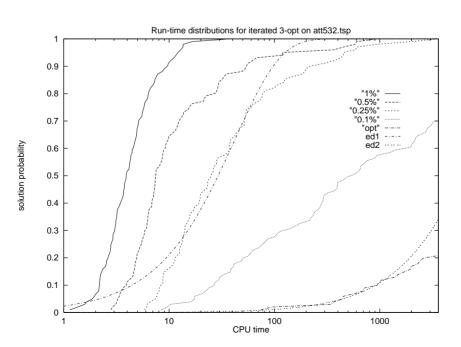

RTD-based analysis of randomised optimisation algorithms:

- Additionally solution quality has to be considered
- introduce bounds on the desired solution quality
 → qualified RTDs
- bounds can be chosen w.r.t. best-known or optimal solutions, lower bounds of the optimal solution cost etc.
- estimate run-time distributions for several bounds on the solution quality

Hoos / Stützle

Stochastic Search Algorithms

SQD-based methodology randomised optimisation algorithms:

- run algorithm multiple times on given problem instance(s)
- estimate empirical solution quality distributions (SQDs) for different run-times
- get simple descriptive statistics (mean, stddev, percentiles, ...) from SQD data
- approximate empirical SQD with known distribution functions
- check statistical significance using goodness-of-fit test

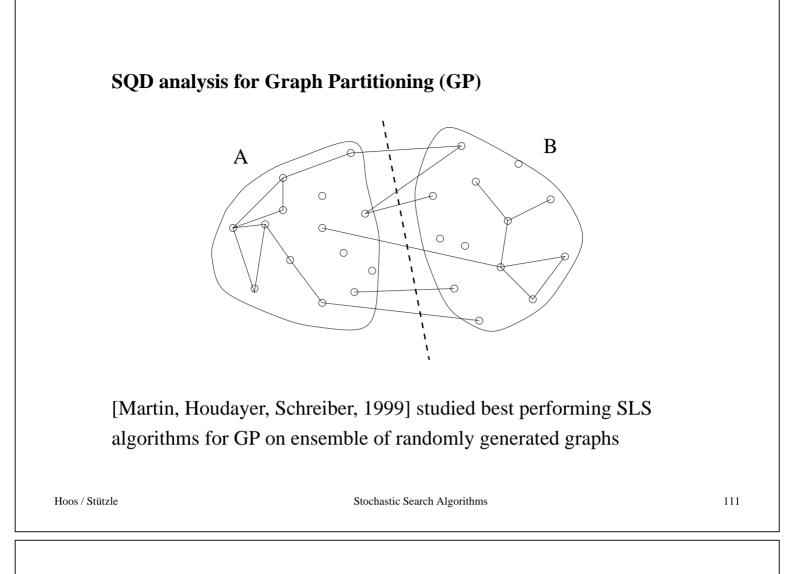

Hoos / Stützle

Stochastic Search Algorithms

109

Questions for SQD-based methodology:

- How do the SQDs scale with increasing run-time?
- What is the limiting shape of the SQDs with increasing instance size

Results:

- SQD distributions approach a limiting Gaussian shape, both within individual graphs and across all graphs
- for increasing instance size the SQD distributions become increasingly peaked
 → solution quality becomes dominating factor when comparing SLS algorithms on large instances
- Similar results also on the TSP

Use solution quality distribution to estimate optimum

given a sample of k feasible solutions and let x be the extreme value from the sample
 → for increasing k, the distribution of x approaches a Weibull distribution with position parameter μ, where μ is optimal solution value [Dannenbring, 1977]

Estimation of optimum possible:

- generate m independent samples of x
- estimate parameters of Weibull distribution
- get confidence interval for optimum

Hoos / Stützle

Stochastic Search Algorithms

113

Search Space Analysis

Intuition:

- algorithm searches in a *fitness landscape* of the problem to be solved
- fitness landscape can be imagined as a mountainous region with hills, craters, valleys ..

Goal: Findest lowest point (for minimization problems)

 \sim analyse structure of the fitness landscape

Fitness landscape is defined by:

- the set of all possible solutions (search space)
- an objective function that assigns to every solution a fitness (objective function) value
- a neighbourhood structure which induces a distance measure between solutions

Distance between solutions:

- defined as the minimum number of moves to convert one solution into another one
- often surrogate distance metrics are used (e.g., distance between tours in the TSP interpreted as number of different edges in two tours)

Hoos / Stützle

Stochastic Search Algorithms

115

Important aspects of fitness landscapes:

- number of local optima
- ruggedness of the fitness landscape
- distribution of local minima and their relative location to the global minima
- topology of basins of attraction of local optima

Search space analysis:

- analysis of search space ruggedness
- analysis of (linear) correlation between solution fitness and distance to global optima (fitness-distance correlation)
 e.g., [Boese 1994, 1996, Jones, Forrest 1995]

Measures for landscape ruggedness:

- autocorrelation function [Weinberger, 1990, Stadler, 1995]
- correlation length [Stadler, 1995]
- autocorrelation coefficient [Angel, Zissimopoulos, 1998, 1999]

Measure for fitness-distance correlation:

• correlation coefficient

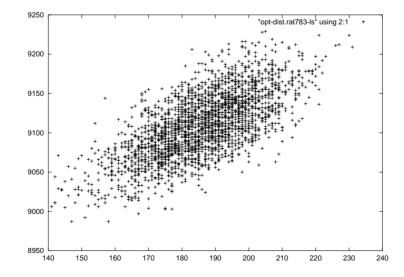

$$\rho(F, D) = \frac{\mathbf{Cov}(F, D)}{\sqrt{\mathbf{Var}(F)} \cdot \sqrt{\mathbf{Var}(D)}}$$

• graphical visualization through plots of fitness-distance relationship

Hoos / Stützle

Stochastic Search Algorithms

Some results for the TSP:

instance	Δ_{avg}	avg_{d-opt}	avg_{d-opt}/n	$ ho_{ls}$
lin318.tsp	3.56	67.25	0.211	0.469
rat783.tsp	4.85	204.24	0.261	0.624
pcb1173.tsp	5.91	274.34	0.234	0.585
pr2392.tsp	5.71	552.49	0.231	0.538

 Δ_{avg} : Percentage deviation from optimum

 avg_{d-opt} : Average distance from optimum

 ρ_{ls} : Correlation coefficient

Hoos / Stützle

Stochastic Search Algorithms

119

Results:

- local minima are contained in a small subspace of the whole search space
- solution fitness guides SLS algorithms towards better solutions

 → the shorter (on average) the tours are, the closer they are to
 the optimal one

Fitness-distance correlations have been analysed for several other problems.

Paramaterisation and Tuning

performance of stochastic search algorithms depends very strongly on appropriate parametrisation and tuning
tuning can be very time-intensive
limited understanding of how performance depends on parameter settings
many stochastic search algorithm leave important implementation choices to the user
experience with stochastic seaech algorithms is required to obtain best performance

Hoos / Stützle

Stochastic Search Algorithms

121

Difficulties with parametrisation

- SLS algorithms are often highly stochastic
 → empirical analysis more difficult
- algorithm parameters are not independent
- seemingly small implementation choices can have significant effects on algorithm behaviour and performance
- . . .

Possible remedies

- use of adequate empirical methodology (statistical techniques) for analysing behaviour
- automatic parameter adjustement during search
 → reactive search

Parallelising Stochastic Search

- randomised algorithms allow extremely easy and scalable parallelisation: multiple independent tries
- effectiveness depends on run-time behaviour of underlying algorithms
- under certain conditions, optimal speedup can be obtained

Hoos / Stützle

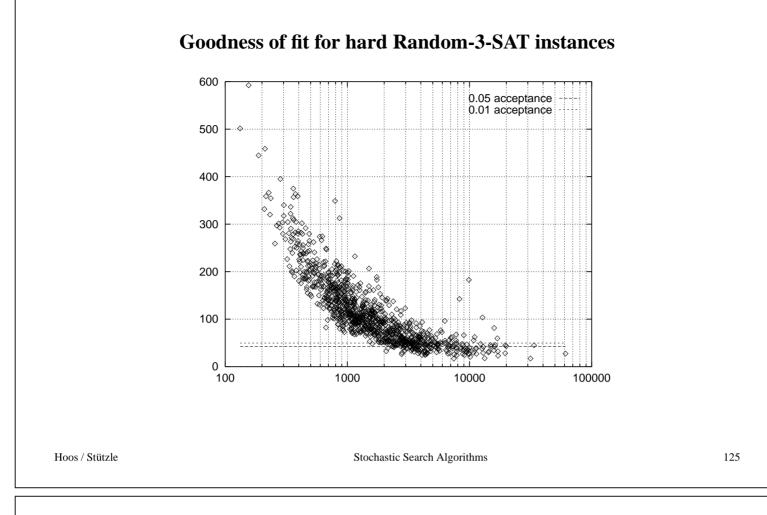

Stochastic Search Algorithms

123

Analysis of the distribution type of RTDs for various well-performing SLS algorithms for a number of problem classes

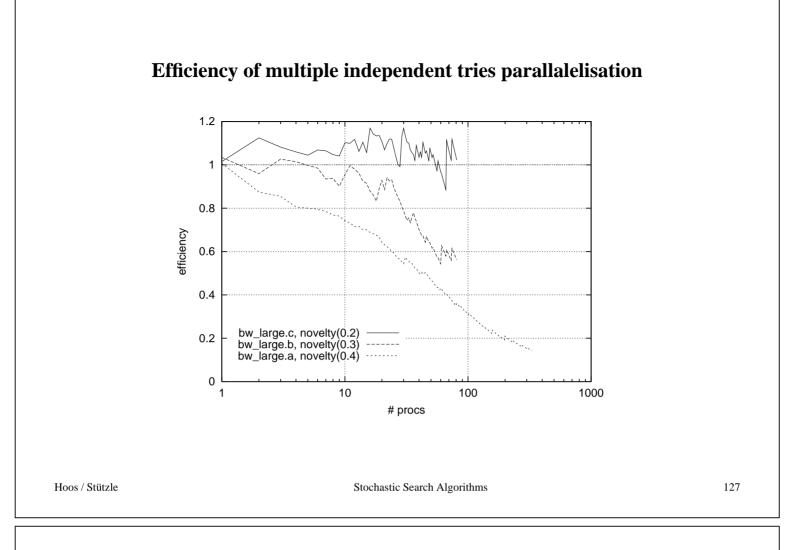

→ Result [Hoos & Stützle 1998]:

For optimal parameterisations and applied to hard problem instances, many state-of-the-art SLS algorithms show exponential run-time distributions (EPAC property).

EPAC property implies:

- search is "memory-less"
 - \sim "random restart" is ineffective
- optimal speedup can be achieved through "multiple independent tries" parallelisation (very easy to implement, almost no communication overhead, arbitrarily scalable)
- new interpretation of SLS behaviour as "random picking" from "virtual search space" (whose size can be computed from RTD data)

ACO algorithms

- fine-grained, not successful
- coarse-grained, more succesful

Genetic Algorithms

- Work on *fine-grained* and *coarse-grained* parallel implementations.

Simulated Annealing

- Parallel Runs
- Evaluation of moves

Tabu Search

- Exponential run-time distributions (QAP)
- Cooperative approaches [Crainic et al.]

Part IV

Applications

Hoos / Stützle

Stochastic Search Algorithms

Applications of Stochastic Search

Some recent successful applications:

- SAT [e.g., Selman et al. 1992–1997, Hoos et. al. 1994–2000]
- TSP [e.g., Johnson & McGeoch 1997, Stützle & Hoos 1997–2000]
- Quadratic Assignment Problem [e.g., Stützle 1997-1999; Taillard 1995]
- Scheduling [e.g., den Besten, Stützle, Dorigo 2000]
- Planning [e.g., Kautz et al. 1996–1999, Brafman & Hoos 1998–2000]
- Combinatorial Auctions [Hoos & Boutilier 2000]

Propositional Satisfiability (SAT)

Progress in SAT solving:

classic SAT solvers: based on 'Davis-Putnam' algorithm (systematic search based on back-tracking)

1990–1992: successful application of SLS algorithms for solving hard SAT instances [Selman et al.; Gu]

1993–1994: new, hybrid SLS strategies with improved performance and robustness [Selman et al.; Gent & Walsh]

1996–1997: further improvements in SLS algorithms [McAllester et al.]; randomised systematic search methods [Gomes et al.]

1998–2000: latest improvements in SLS algorithms, based on GLSM model [Hoos & Stützle]

Hoos / Stützle

Stochastic Search Algorithms

131

SLS algorithms for SAT

- search through space of complete variable assignments
- solutions = models of the given formula
- two assignments are neighbours if they differ in the value of exactly one variable
- evaluation function is the number of clauses unsatisfied under a given assignment

- search initialisation: randomly chosen assignment
- search steps: algorithm dependent, use random choices and/or tie-breaking rules
- most algorithms use random restart if no solution has been found after a fixed number of search steps

Stochastic Search Algorithms

The GSAT Algorithm [Selman, Mitchell, Levesque, 1992]

- in each search step, flip the variable which gives the maximal increase (or minimal decrease) in the number of unsatisfied claused
- ties are broken randomly
- if no model found after *maxSteps* steps, restart from randomly chosen assignment

The GWSAT Algorithm [Selman, Kautz, Cohen, 1994]

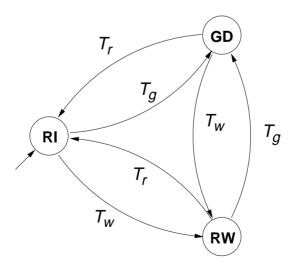

- search initialisation: randomly chosen assignment
- Random Walk step: randomly choose a currently unsatisfied clause and a literal in that clause, flip the corresponding variable to satisfy this clause
- GWSAT steps: choose probabilistically between a GSAT step and a Random Walk step with 'walk probability' (noise) *wp*

Hoos / Stützle

Stochastic Search Algorithms

135

GLSM representation of GWSAT

The WalkSAT algorithm family [McAllester et al., 1997]

- search initialisation: randomly chosen assignment
- search step
 - 1. randomly select a currently unsatisfied clause
 - 2. select a literal from this clause according to a heuristic h
- if no model found after *maxSteps* steps, restart from randomly chosen assignment

Stochastic Search Algorithms

Some WalkSAT algorithms

- **SKC:** Select variable such that minimal number of currently satisfied clauses become unsatisfied by flipping; if 'zero-damage' possible, always go for it; otherwise, with probability *wp* variable is randomly selected.
- **Tabu:** Select variable that maximises increase in total number of satisfied clauses when flipped; use constant length tabu-list for flipped variables and random tie-breaking.

Novelty: Order variables according to increase in total number of satisfied clauses when flipped; if best variable in this ordering not most recently flipped, always go for it; otherwise, select second-best with probability wp.

R-Rovelty: Similar to Novelty, but more complex decision between the variable with best and second-best score.

Hoos / Stützle

Stochastic Search Algorithms

139

Some properties of these algorithms

[Hoos & Stützle 1998-1999, Hoos 1999]:

- SKC, Tabu, Novelty, and R-Novelty: exponential run-time distributions when applied to hard SAT instances and using optimal (or greater-than-optimal) noise settings
 → optimal parallelisation
- Tabu, Novelty, and R-Novelty: essentially incomplete, i.e., can get stuck in non-solution areas of search space.

Novelty⁺ and R-Novelty⁺ [Hoos 1998]:

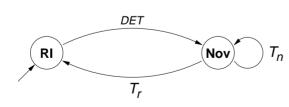

- extend Novelty, R-Novelty with (unconditional) Random Walk — simple generic modification of the corresponding GLSM
- resulting algorithms are probabilistically approximately complete
- significantly improved performance & robustness

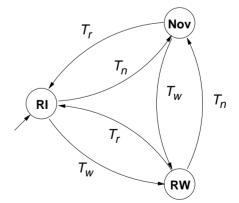

These algorithms are amongst the best-performing algorithms for SAT known today; they solve hard instances up to > 10,000 variables and > 100,000 clauses.

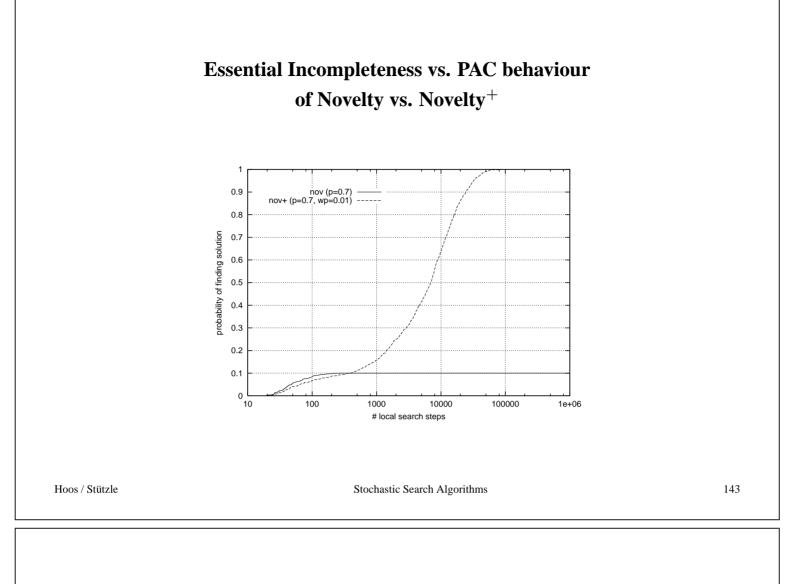

Hoos / Stützle

Stochastic Search Algorithms

GLSM representations of Novelty vs. Novelty⁺

Some other stochastic search approaches for SAT:

- simulated annealing [Spears, 1993; Beringer et al., 1994]
- genetic algorithms [Frank, 1994]
- GRASP [Feo & Resende, 1996]
- simple learning strategies for SLS [Selman & Kautz, 1993; Frank, 1997; Boyan & Moore 1998]
- REL_SAT [Bayardo & Schrag, 1997]

Similar SLS algorithms are successfully used to solve more general problems:

- MAX-SAT [e.g., Hansen & Jaumard, 1990; Battiti & Protasi, 1997]
- CSP [e.g., Minton et al., 1990–1992; Stützle, 1997; Galinier, Hao 1997]
- Dynamic SAT [Hoos & O'Neill, 2000]

Hoos / Stützle

Stochastic Search Algorithms

145

The Travelling Salesman Problem (TSP)

The TSP ...

- has been a source of inspiration for new algorithmic ideas
- is a standard test-bed for exact and approximate algorithms

Recent contributions to TSP solving:

- finding approximate solutions of very high quality
- pushing the frontier of tractable instance size
- understanding of algorithm behaviour

Approaches for the TSP:

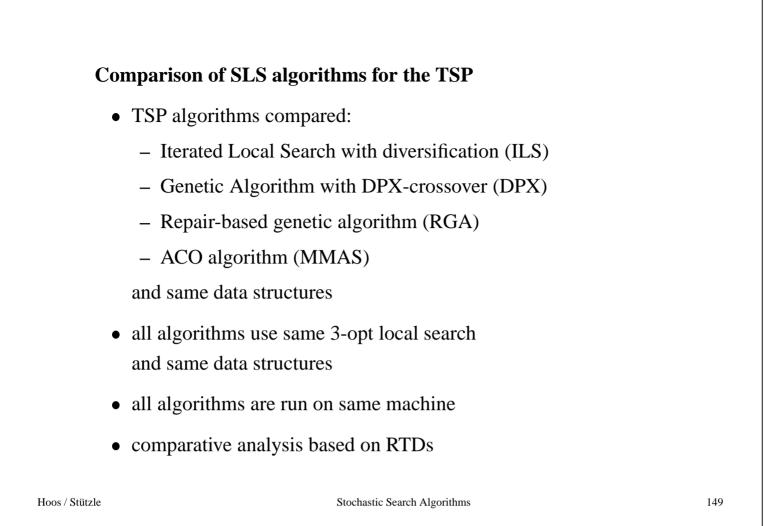

- Exact Algorithms: Branch & Cut
 → largest instance solved has 13,509 cities!
- SLS algorithms:
 - construction heuristics
 - iterative improvement algorithms
 - metaheuristics

Hoos / Stützle

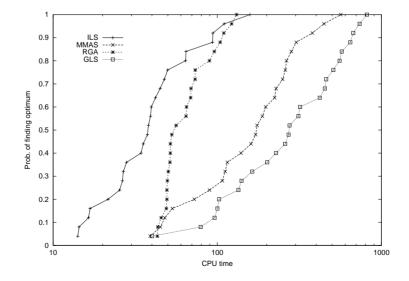

Stochastic Search Algorithms

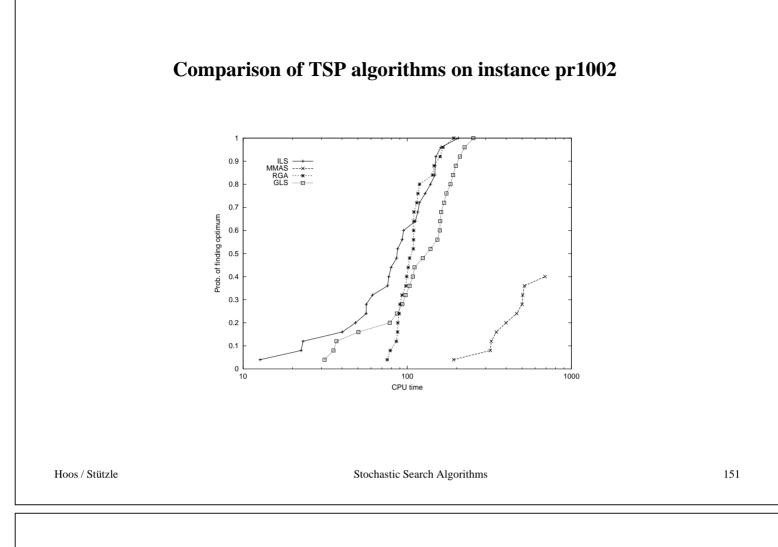

Results for SLS algorithms:

- construction heuristics and iterative improvement can be applied to very large instances (> 10⁶ cities) with considerable success [Applegate et al. 2000, Johnson, McGeoch 1997]
- best performance results w.r.t. solution quality obtained with iterated local search, genetic algorithms, or more TSP-specific approaches [Applegate et al., 2000, Johnson, McGeoch, 1997, Merz, Freisleben, 1997, Stützle, Hoos, 1999]
- best performing hybrid algorithms use 3-opt or Lin-Kernighan local search
- instances with < 1000 cities can regularly be solved to optimality within few minutes

Comparison of TSP algorithms on instance rat783

Results:

- very good performance by all algorithms
- no algorithm dominates all others on all instances
- ILS algorithm performs best on most instances
- all algorithms need effective diversification features to achieve best performance
- additional experiments with other 3-opt implementations of 3-opt showed that specific implementation details can result in significant performance difference
- some RTDs are "steeper" than an exponential distribution

The Quadratic Assignment Problem (QAP)

Given:

- *n* items to be assigned to *n* locations
- a_{ij} : Flow from item *i* to item *j*
- d_{rs} : Distance between location r and location s

Objective: Minimise sum of products flow \times distance

Hoos / Stützle

Stochastic Search Algorithms

The QAP ...

- is a generic problem in layout design
- has applications in hospital layout, typewriter keybord design, ...
- is considered to be one of the "hardest" optimization problems for exact solution

 \rightsquigarrow need for approximate solution

Local search algorithms for the QAP

- search space given by all possible assignments, represented by permutations
- assignments are neighboured if they differ in the location of exactly two items

SLS approaches for the QAP

- SA, TS, ILS, EA, ACO have all been to the QAP
- several additional approaches to the QAP
- relative performance depends strongly on instance characteristics

Hoos / Stützle

Stochastic Search Algorithms

155

Four classes of QAP instances in QAPLIB [Taillard, 1995]

- randomly generated instances according to uniformly distributed matrix entries (class I)
- random flows on grids (class II)
- real-life problems (class III)
- randomly generated problems which resemble the structure of real-life problems (class IV)

Indication of type

• flow and/or distance dominance

$$fd(A) = 100 \cdot \frac{\sigma}{\mu}$$
, where

$$\mu = \frac{1}{n^2} \cdot \sum_{i=1}^n \sum_{j=1}^n a_{ij}; \ \sigma = \sqrt{\frac{1}{n^2 - 1} \cdot \sum_{i=1}^n \sum_{j=1}^n (a_{ij} - \mu)}$$

• sparsity of flow and/or distance matrix

Hoos / Stützle

Stochastic Search Algorithms

157

Fitness-Distance Analysis

- instances of class I show no significant fitness-distance correlations
- most of the instances of classes II and III do have significant fitness-distance correlations; the largest correlations are observed for instances of classes III and IV
- local minima are spread over the whole search space
- some instances have many optimal solutions
- dominance and sparsity give indication of instance type

Case study: ACO algorithm ($\mathcal{M}\mathcal{M}AS$) for the QAP

- ACO algorithm constructs solutions by iteratively assigning items to locations
- pheromone trails τ_{ij} refer to the desirability of assigning item i to location j
- solution construction only uses pheromone trails
- solutions are improved by local search

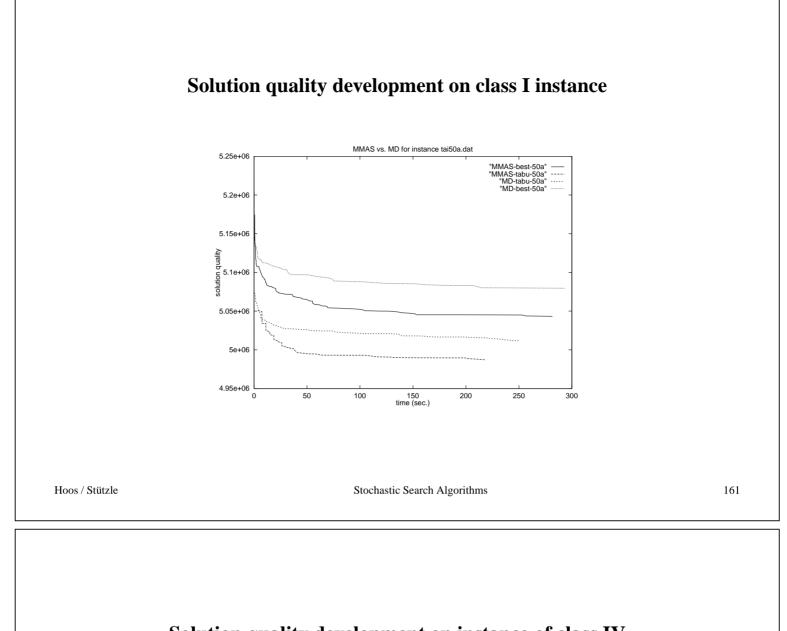

Hoos / Stützle

Stochastic Search Algorithms

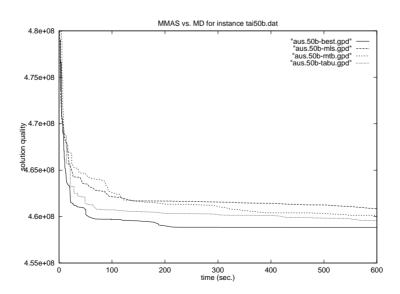

Which type of local search to be used?

- 2-opt local search algorithm (*MMAS*_{2-opt})
 → needs only few steps to reach local minimum
- short tabu search runs (*MMAS*_{TS})
 → more run-time intensive than 2-opt but finds solutions of higher quality than 2-opt

Tradeoff: Speed vs. Quality

Solution quality development on instance of class IV

Computational comparison of QAP algorithms

- algorithms compared are among the best known for the QAP:
 - robust tabu search (Ro-TS): long runs of same TS used \mathcal{MMAS}_{TS} [Taillard, 1991, 1995]
 - genetic hybrids (GH): genetic algorithm using the same TS algorithm as \mathcal{MMAS}_{TS} [Fleurent, Ferland, 1994]
 - hybrid ant system (HAS) [Gambardella et al., 1999]
 - \mathcal{MMAS}_{TS} and \mathcal{MMAS}_{2-opt} [Stützle, Hoos, 1997-2000]
- algorithms use approx. same computation time
- results are given as the average deviation from best known solutions over 10 independent algorithm runs

Hoos / Stützle

Hoos / Stützle

Stochastic Search Algorithms

165

Results:

- relative performance of algorithms depends strongly on instance class
- frequent application of a fast local search performs better on more structured instances
- $\mathcal{M}\mathcal{M}AS$ among best algorithms for the QAP

Scheduling

Scheduling: allocation of limited resources to tasks over time

Resources: examples are machines in a workshop, runways at airport, . . .

Tasks: examples are operations in a production process, take-offs and landings at an airport, . . .

Objectives: usually depending on the tasks completion time, shipping dates to be met, . . .

Stochastic Search Algorithms

The Single Machine Total Weighted Tardiness Problem

Often, single machine is the bottleneck in production environment.

Given (for each item):

- due date d_j given for each task
- weight (importance) w_j for each single task
- processing time p_j for each task

Objective: minimise sum of weighted tardiness

(tardiness = surtime a task is completed after its due date)

The SMTWTP is \mathcal{NP} *-hard.*

Stochastic Search Algorithms

Local search algorithms for SMTWTP several construction heuristics available search space given by all possible task sequences possible neighbourhoods: swaps of two neighboring jobs at position *i* and *i* + 1 *swap-neighbourhood*interchanges of jobs at *i*th and *j*th position *interchange-neighbourhood*removals of job at *i*th position and insertion in *j*th position *insert-neighbourhood*

Hoos / Stützle

Stochastic Search Algorithms

169

More effective local search

- *Observation:* local optimum w.r.t. one neighbourhood need not be a local optimum for another neighbourhood relation
- *Idea:* concatenate local search in different neighbourhoods this idea is systematically exploited in variable neighbourhood search [Mladenovic, Hansen, 1995–2000]
- *Tests:* effectiveness of concatenating interchange and insert neighbourhood with different construction heuristics
- *Instances:* 125 randomly generated benchmark instances with 40, 50, and 100 tasks; results are averaged over the benchmark instances

constr.	no le	ocal sea	arch	interchange			insert		
heuristic	Δ_{avg}	n _{opt}	t_{avg}	Δ_{avg}	n_{opt}	t_{avg}	Δ_{avg}	n_{opt}	t_{avg}
EDD	135	24	0.001	0.62	33	0.140	1.19	38	0.64
MDD	61	24	0.002	0.65	38	0.078	1.31	36	0.77
AU	21	21	0.008	0.92	28	0.040	0.56	42	0.26
	constr.		inter+ins	ert	insert+inter

	EDD	0.2	24 46	0.20	0.47	48	0.67		
	MDD	0.4	40 46	0.14	0.44	42	0.79		
	AU	0.5	59 46	0.10	0.21	49	0.27		

 Δ_{avg} : avg. deviation from best known, n_{opt} : No. of best known solutions found t_{avg} : avg. computation in seconds on Pentium II 266MHz

Hoos / Stützle

Stochastic Search Algorithms

171

Results:

- concatenated local search significantly more effective
 → more complex neighbourhood yields more effective local search
- other local search extension: Dynasearch [Congram, Potts, van de Velde 1998]
- final solution quality depends strongly on starting solution
- improvements possible by hybrid algorithms
 → extensions using ILS and ACO

- solution modification: variable number of random left-insert moves
- acceptance criterion: Apply solution modification to best solution since start of the algorithm
- local search: several possibilities examined, best results with interchange-insert concatenation

Stochastic Search Algorithms

ACO algorithm

- solutions are constructed starting from an empty sequence by iteratively appending tasks
- pheromone trail τ_{ij} refers to desirability of assigning task *i* to position *j*
- solution construction uses pheromone trails and heuristic information
- local search: half the colony applies insert-interchange, the other half interchange-insert local search

Summary of results

- excellent performance of both approaches
- they consistently find best-known solutions on all known benchmark instances in reasonable time (few seconds up to some minutes)
- heterogeneous colony in ACO improved robustness
- ILS on most instances faster than ACO
- benchmark instances obtained with specific parameter settings for instance generator are very easily solved
- search space analysis could identify reasons for good performance

Hoos / Stützle

Stochastic Search Algorithms

Planning

Given: set of actions (operators), initial and goal state

Objective: find sequence (or partially ordered collection) of a actions which allow to reach goal state from initial state

Some prominent AI planning problems:

- blocks world
- logistics
- configuration

Planning is an NP*-hard combinatorial problem.*

Some algorithms for planning:

- classic approaches: forward planning / regression planning
- GraphPlan [Blum & Furst, 1995]
- SATPLAN, Blackbox [Kautz & Selman, 1996-1999]
- LPSP [Brafman & Hoos, 1998-1999]

Hoos / Stützle

Stochastic Search Algorithms

177

The Planning-as-SAT approach:

- encode planning instance into SAT (given fixed/max plan length)
- use polynomial preprocessing to simplify SAT instance (unit propagation, subsumption, etc.)
- use SAT algorithm to solve simplified SAT instance (WalkSAT, satz, etc.)
- decode propositional model into plan

Advantages:

- highly competitive with best known general purpose planners [Kautz & Selman, 1996]
- makes use of very advanced propositional reasoning technology
- benefits from any improvements in SAT solving (software & hardware)

Potential disadvantages:

- potentially more difficult to integrate domain-specific knowledge
- very large, explicit intermediate representations (CNF formulae)
- overhead through encoding / decoding

Hoos / Stützle

Stochastic Search Algorithms

179

Lifting SLS techniques to plan level:

- search directly in a space of candidate plans
- use SLS techniques for SAT at plan level
- add new, planning specific SLS strategies (GLSM states)

→ LPSP algorithm for linear planning [Brafman & Hoos, 1998–1999]

Search initialisation: Bi-directional stochastic search (construction heuristic)

Search steps:

Best-Replacement: replace single action such that a maximal number of flaws (unsatisfied preconditions of actions) is removed from the current plan

Flaw-Repair: randomly chose a flaw from the current plan and repair it by replacing a single action

Reorder: reorder current plan heuristically, trying to minimise number of flaws and throwing out superfluous actions

Additionally: use reachability analysis as preprocessing step to prune out impossible actions

Hoos / Stützle

Stochastic Search Algorithms

instance	plan length	LPSP		WalkS	satz	
		mean	vc	mean	vc	
bw_large.a	6	0.096	0.53	0.73	n/a	0.56
bw_large.b	9	1.22	0.82	3.61	0.88	1.44
bw_large.c	14	4.62	0.61	62.96	0.99	5.82
bw_large.a	18	31.18	0.60	152.05	0.94	> 60
log.a	6	0.068	0.48	4.33	n/a	4.33
log.b	10	0.69	1.37	11.56	n/a	11.58
log.c	16	13.50	1.11	1,075.17	0.67	> 60

Run-time of LPSP vs. SATPLAN

Advantages:

- excellent performance for linear planning
- facilitates combination of general-purpose and domain-specific SLS strategies
- avoids large intermediate representations
- easier to analyse / understand

Disadvantages:

- more complex, planning specific SLS algorithm
- more difficult to implement
- allows less use of "off-the-shelve" solver technology

Hoos / Stützle

Stochastic Search Algorithms

183

Combinatorial Auctions

Auctions are attractive as mechanisms for ...

- E-commerce (business transactions, sales)
- resource allocation (radio frequencies, pollution rights, scheduling)
- coordinating agents in multi-agent systems
- \rightsquigarrow increasing interest in CS / AI

Standard, single item auctions:

- winner determination is easy
- cannot express complementarities of goods

Combinatorial auctions (CAs):

- bidding for bundles
- allows to express preferences more directly
- minimises buyer's risk of getting incomplete combinations

Hoos / Stützle

Stochastic Search Algorithms

185

Example: (fictitious — at least for now)

Driving rights (polution control / restricted traffic capacity): people bid for the guarantee to drive their car on a autobahn on certain days.

Bidder A wants to go to from Berlin to Bremen over the weekend, thus has to bid for Fri and Sun autobahn access.

 \sim A needs both access permits (=bundle of items)

Winner determination for CAs

Given:

- set of goods to be auctions
- set of bids for combinations (sets) of these goods

Problem:

Determine assignment of goods to bidders maximising total revenue (sum of prices for satisfied bids).

Stochastic Search Algorithms

SLS algorithms for CA

search space: space of feasible, partial assignments

solution set: assignments with optimal / given revenue

neighbourhood relation: assignments reachable by reassigning set of goods such that one formerly unsat bid becomes satisfied

search initialisation function: start with empty assignment

search step function: picks a neighbour according to stochastic heuristic h

[Hoos, Boutilier 2000]

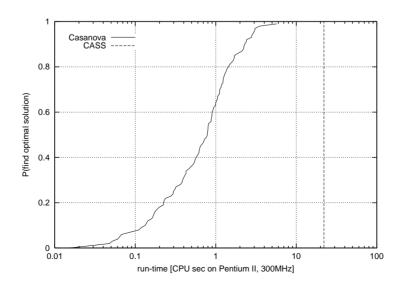

Casanova, one algorithm of this family ...

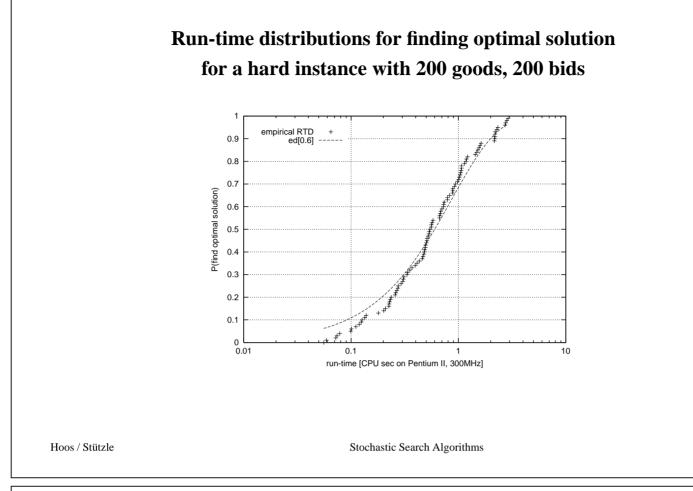

- was designed based on principles and methods developed and tested for SLS algorithms for SAT
- outperforms best known algorithm for CA (CASS) for large problems with fixed cutoff times significantly
- although incomplete, finds optimal solutions to small CA instances, often much faster than systematic search
- scales better with growing problem size than other methods
- can be easily parallelised with optimal speedup

Hoos / Stützle

Stochastic Search Algorithms

Run-time distributions for finding optimal solution for a hard instance with 100 goods, 100 bids

Average Revenue for CASS vs. Casanova
(fixed run-time)

problem type	# goods	# bids	CASS	Casanova	Gain
simple uniform (3)	200	10000	281413	286164	1.69%
simple binomial (0.01)	500	5000	583279	616708	5.73%

cnf uniform (3)	100	100	104868	127011	21.12%
cnf poisson (2)	100	500	101568	135973	33.87%
k-of uniform (2,4,2)	100	100	48812	59938	22.79%

Conclusions and Issues for Future Research

Hoos / Stützle

Stochastic Search Algorithms

193

Conclusions

- Stochastic search is one of the most efficient approaches for solving combinatorial problems in practice
- Studying stochastic search algorithms for conceptually simple domains, such as SAT or TSP, facilitates development, analysis, and understanding of algorithms
- Advanced empirical methodology helps to characterise and exploit stochastic search behaviour based on computational experiments
- Lots of potential application areas, lots of interesting research questions

Future Work

- further advance understanding of stochastic search behaviour
 (→ search space analysis, new theoretical & empirical results)
- further improvements in stochastic search algorithms
 (~> hybrid algorithms, adaptive algorithms)
- application to real-world problems
 (e.g., intelligent systems, e-commerce, bioinformatics)

Hoos / Stützle

Stochastic Search Algorithms

195

Stochastic search is a general approach for solving combinatorial problems with significant research and practical potential, *but:* it is certainly no panacea.
