

# CPSC 425: Computer Vision

**Lecture 13:** Correspondence and SIFT

# Menu for Today

## Topics:

- **Correspondence** Problem
- **Invariance**, geometric, photometric
- **Patch** matching
- **SIFT** = Scale Invariant Feature Transform

## Readings:

- **Today's** Lecture: Szeliski Chapter 7, Forsyth & Ponce 5.4

## Reminders:

- **Midterm** — will be graded next week
- **Assignment 3**: Texture Synthesis due on **Sunday** (not today)
- **Assignment 4**: RANSAC and Panorama Stitching out **Today**

# Scale Invariant Feature Transform = SIFT

## Distinctive Image Features from Scale-Invariant Keypoints

David G. Lowe  
Computer Science Department  
University of British Columbia  
Vancouver, B.C., Canada  
lowe@cs.ubc.ca

January 5, 2004

### Abstract

*This paper presents a method for extracting distinctive invariant features from images that can be used to perform reliable matching between different views of an object or scene. The features are invariant to image scale and rotation, and are shown to provide robust matching across a substantial range of affine distortion, change in 3D viewpoint, addition of noise, and change in illumination. The features are highly distinctive, in the sense that a single feature can be correctly matched with high probability against a large database of features from many images. This paper also describes an approach to using these features for object recognition. The recognition proceeds by matching individual features to a database of features from known objects using a fast nearest-neighbor algorithm, followed by a Hough transform to identify clusters belonging to a single object, and finally performing verification through least-squares solution for consistent pose parameters. This approach to recognition can robustly identify objects among clutter and occlusion while achieving near real-time performance.*

Accepted for publication in the *International Journal of Computer Vision*, 2004.

The SIFT paper (David Lowe) was rejected twice (and eventually published only as a Poster). Became one of the most **influential** and **widely cited papers** in the field ~ 70,000 citations.

# Correspondence Problem

A basic problem in Computer Vision is to establish matches (correspondences) between images.

This has **many** applications: rigid/non-rigid tracking, object recognition, image registration, structure from motion, stereo...

# Image Panoramas

# Building Rome in a Day

**The Colosseum:** 2,106 images, 819,242 points matched

# Intensity Image

Just use the pixel values of the patch

Perfectly fine if geometry and appearance is unchanged  
(a.k.a. template matching)

What are the problems?

# Intensity Image

Just use the pixel values of the patch

Perfectly fine if geometry and appearance is unchanged  
(a.k.a. template matching)

What are the problems?

How can you be less sensitive to absolute intensity values?

# Image Gradients / Edges

Use pixel differences

Feature is invariant to absolute intensity values

What are the problems?

# Image Gradients / Edges

Use pixel differences

Feature is invariant to absolute intensity values

What are the problems?

How can you be less sensitive to deformations?

# Geometric Transformations

objects will appear at different scales,  
translation and rotation

# Geometric Transformations

How can we deal with this?

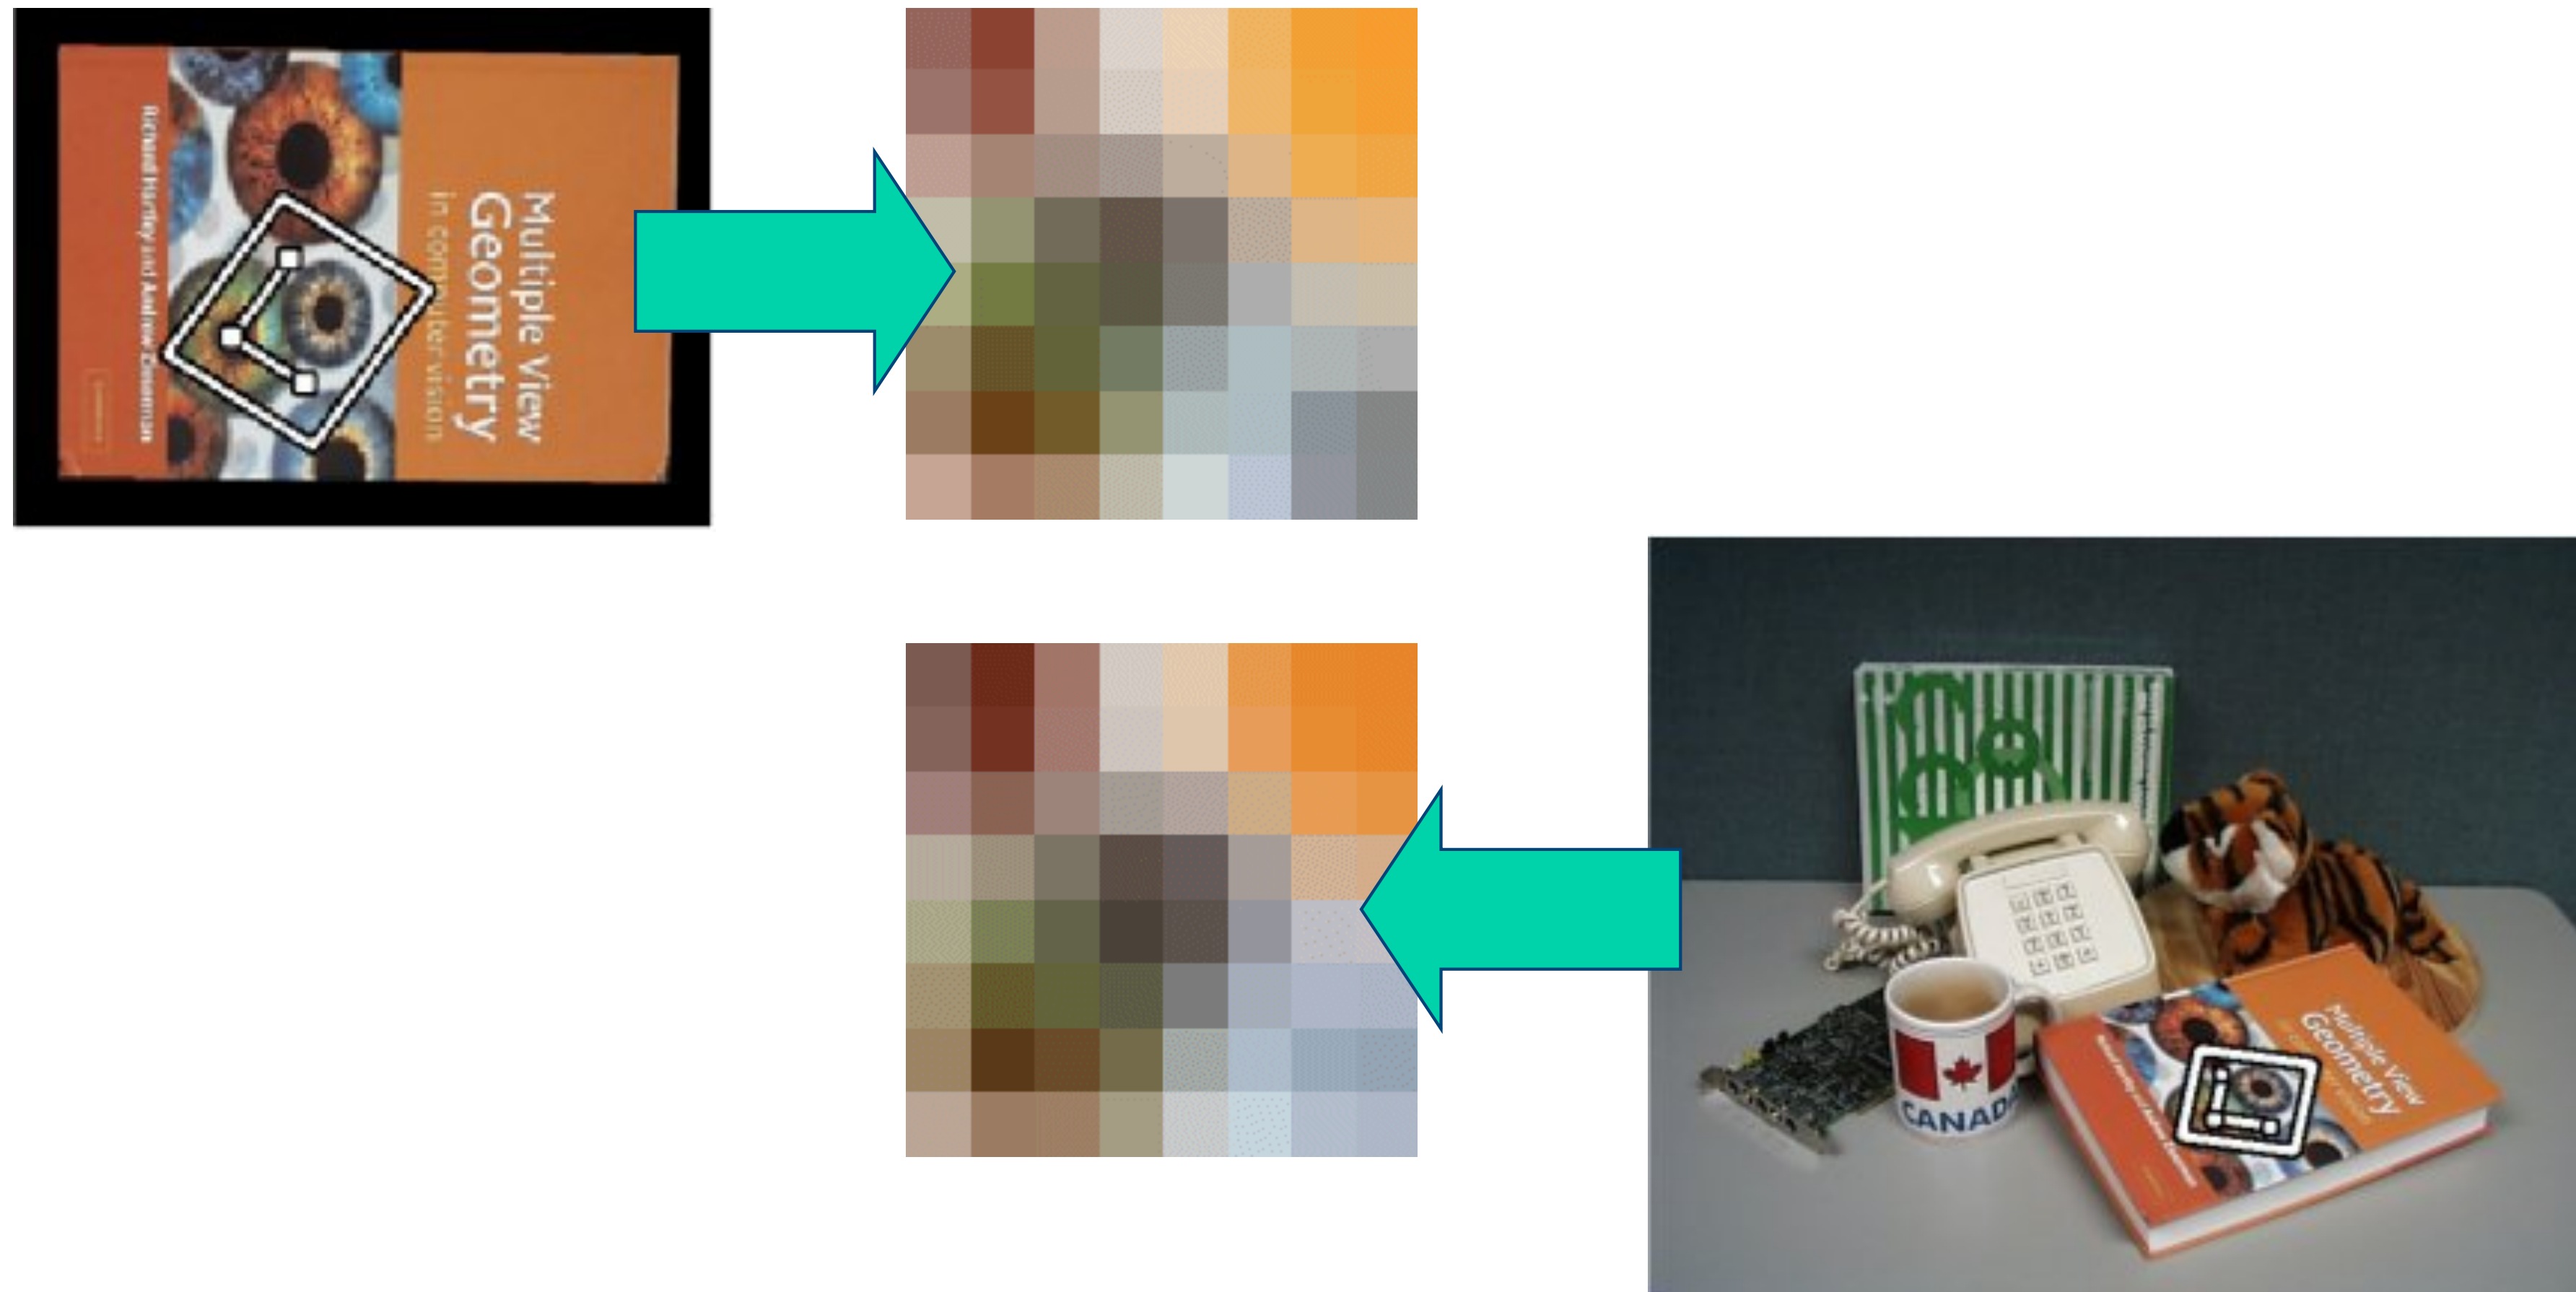

objects will appear at different scales,  
translation and rotation

# Local Coordinate Frame

One way to achieve invariance is to use **local coordinate frames** that follow the surface transformation (covariant) and compute features descriptors in them

# Strategy #1: Detecting **Scale** / **Orientation**

A common approach is to detect a local scale and orientation for each feature point

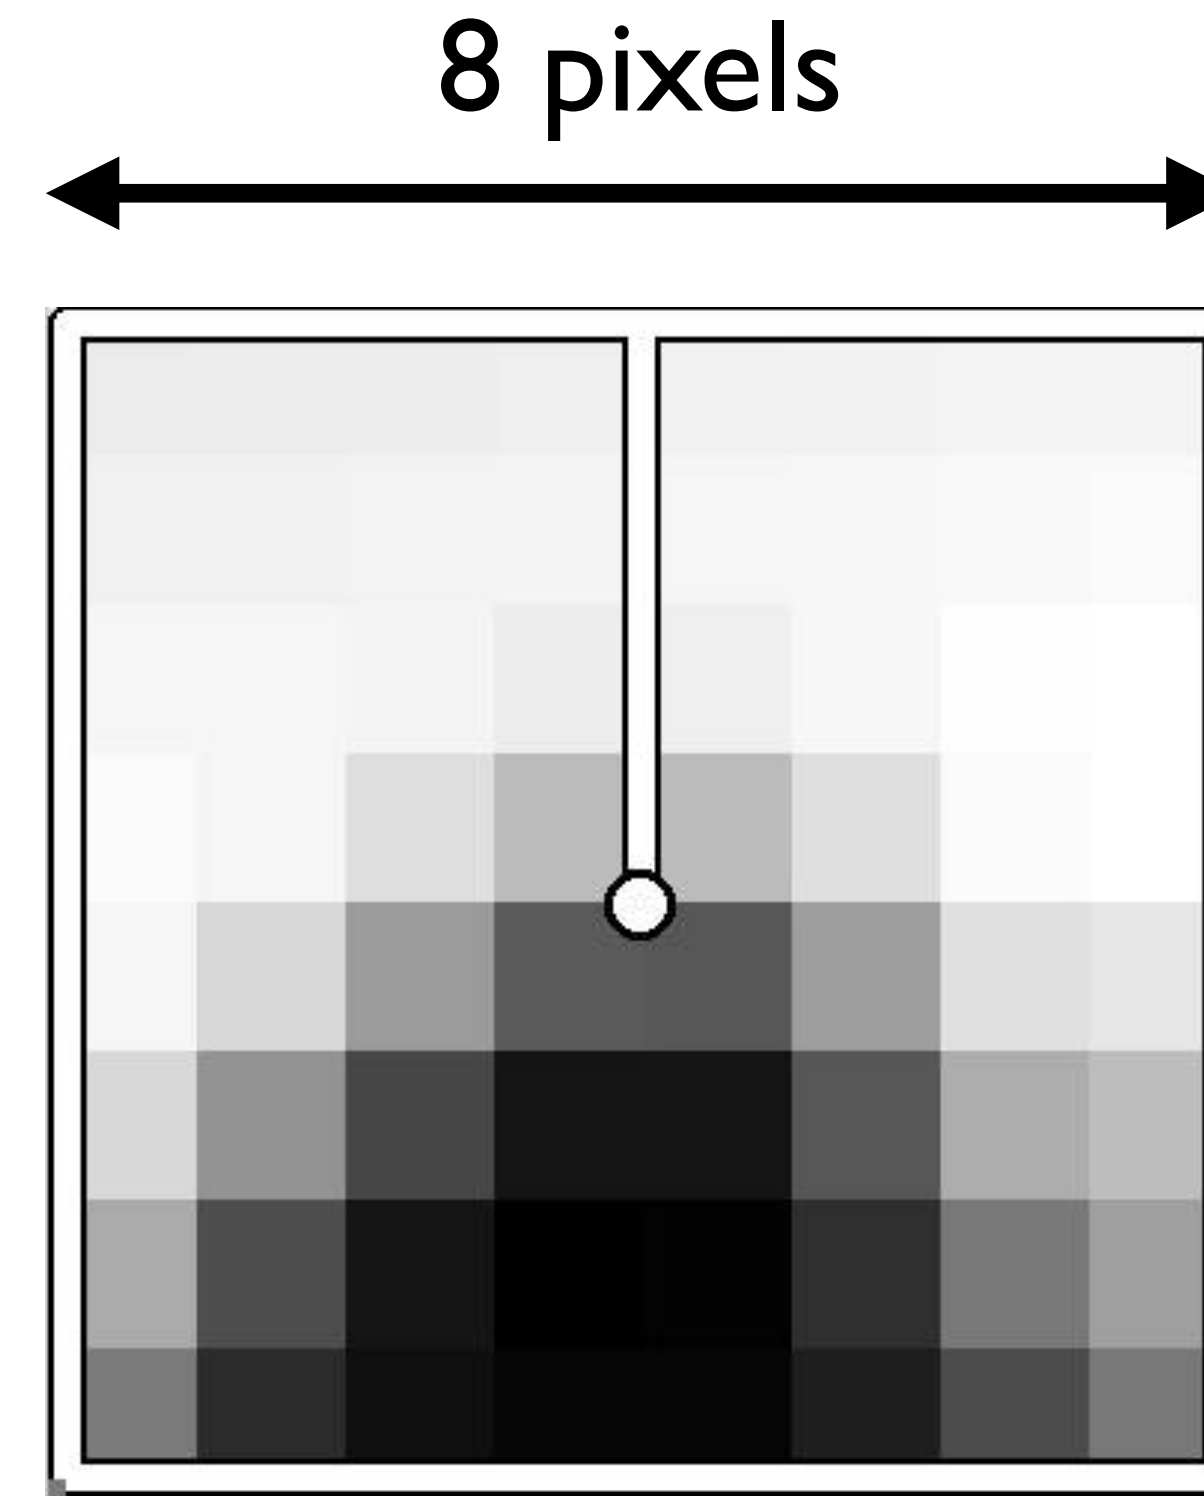

e.g., extract Harris at multiple scales and align to the local gradient

# Strategy #1: Detecting Scale / Orientation

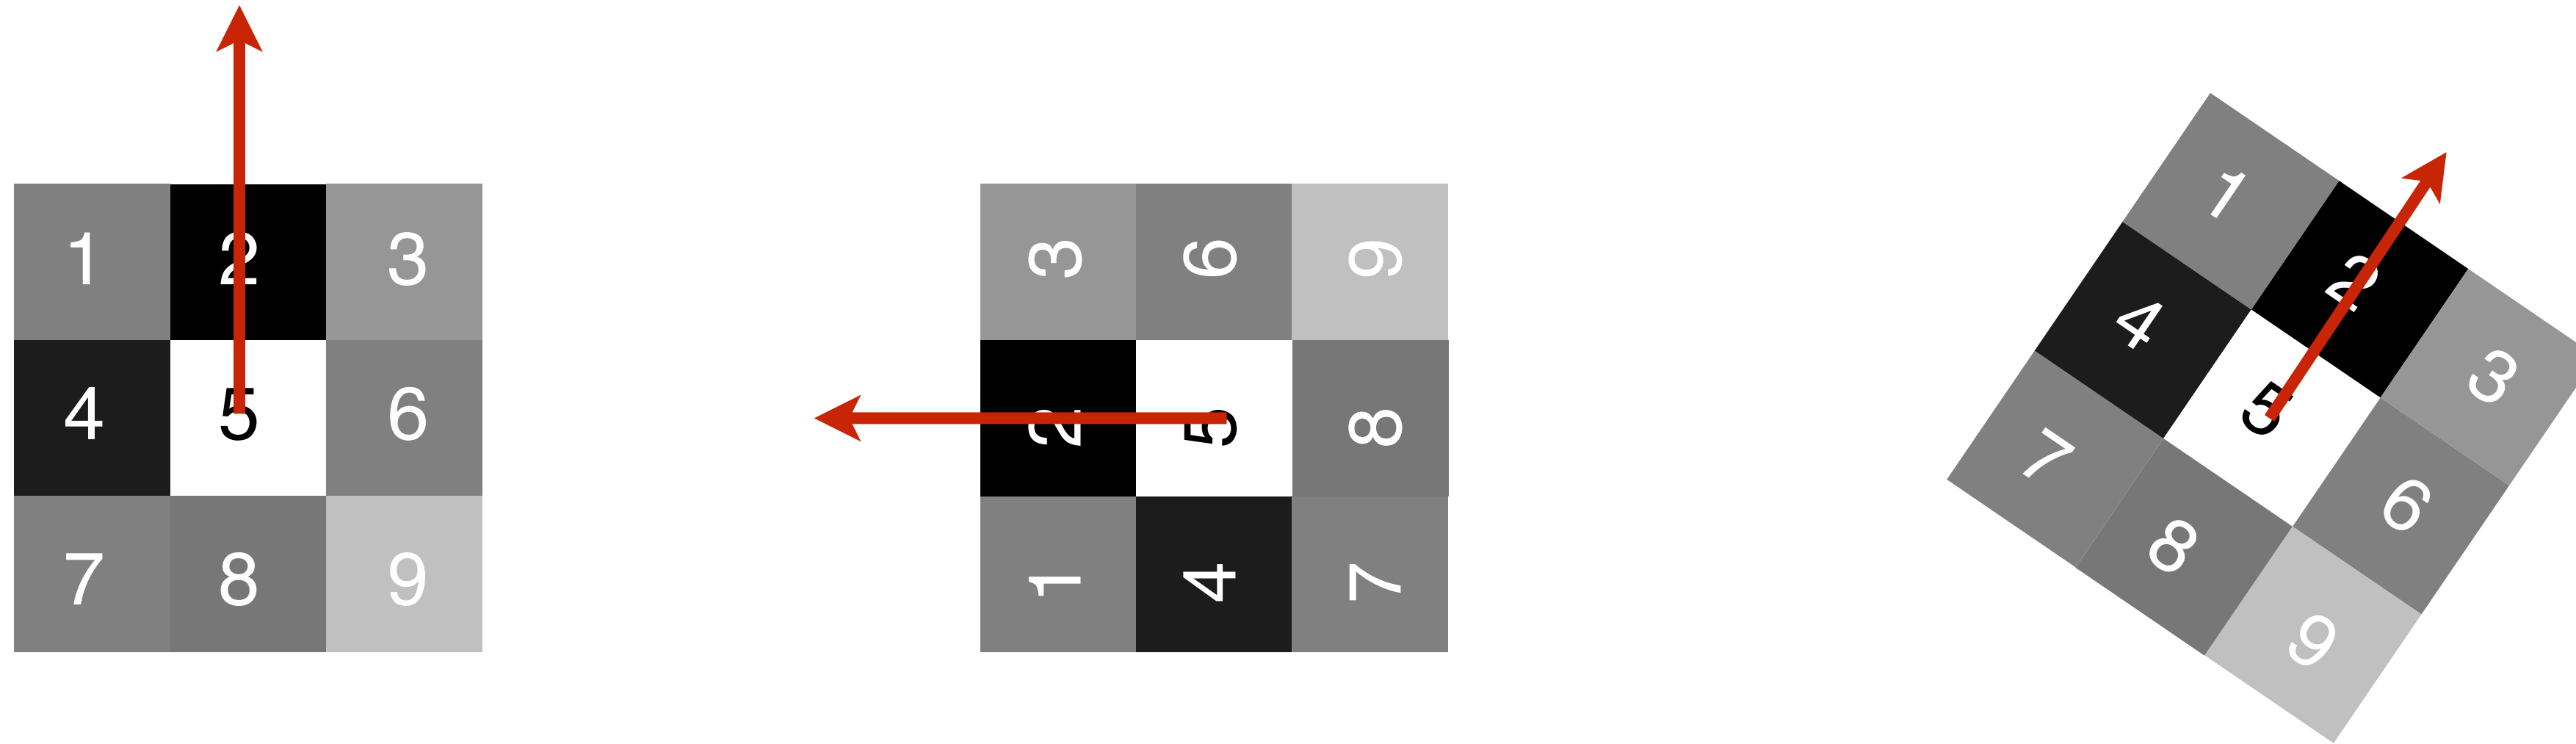

A common approach is to detect a local scale and orientation for each feature point

e.g., extract Harris at multiple scales and align to the local gradient

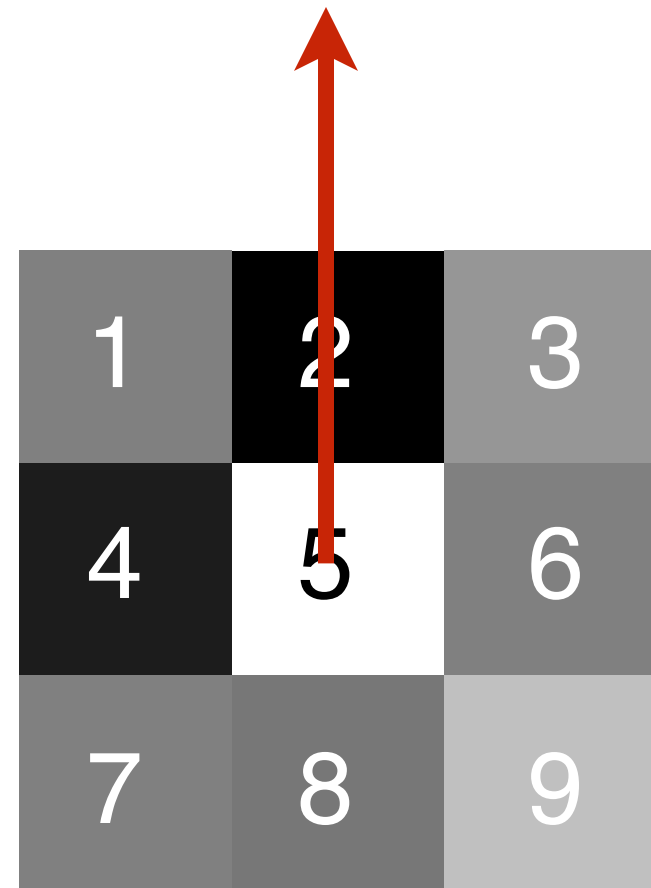

# Strategy #1: Compute Features in Local Coordinate Frame

First rotate to canonical frame of reference (e.g., align feature direction with y-axis) and only then compute a feature representation

# Strategy #1: Compute Features in Local Coordinate Frame

First rotate to canonical frame of reference (e.g., align feature direction with y-axis) and only then compute a feature representation

# Strategy #1: Compute Features in Local Coordinate Frame

First scale to canonical frame of reference and only then compute a feature representation

# Strategy #1: Compute Features in Local Coordinate Frame

1	2	3
4	5	6
7	8	9

1	2	3
4	5	6
7	8	9

1	2	3
4	5	6
7	8	9

First scale to canonical frame of reference and only then compute a feature representation

# Strategy #2: Represent Distributions over Gradients

Use pixel differences

Feature is invariant to absolute intensity values

# Where does **SIFT** fit in?

Representation	Result is...	Approach	Technique
intensity	dense (2D)	template matching	(normalized) correlation, SSD
edge	relatively sparse (1D)	derivatives	$\nabla^2 G$ , Canny
“corner” / “blob”	sparse (0D)	locally distinct features	Harris, <b>SIFT</b>

# Object **Recognition** with Scale Invariant Feature Transform

**Task:** Identify objects or scenes and determine their pose and model parameters

## **Applications:**

- Industrial automation and inspection
- Mobile robots, toys, user interfaces
- Location recognition
- Digital camera panoramas
- 3D scene modeling, augmented reality

# David Lowe's Invariant Local Features

# David Lowe's Invariant Local Features

Image content is transformed into local feature coordinates that are invariant to translation, rotation, scale, and other imaging parameters

# Advantages of Invariant Local Features

**Locality:** features are local, so robust to occlusion and clutter (no prior segmentation)

**Distinctiveness:** individual features can be matched to a large database of objects

**Quantity:** many features can be generated for even small objects

**Efficiency:** close to real-time performance

# Scale Invariant Feature Transform (**SIFT**)

# 1. Multi-scale Extrema Detection — Sampling Frequency

More points are found as sampling frequency increases, but accuracy of matching decreases after 3 scales/octave

## 2. Keypoint Localization

- After keypoints are detected, we remove those that have **low contrast** or are **poorly localized** along an edge

## 2. Keypoint Localization

— After keypoints are detected, we remove those that have **low contrast** or are **poorly localized** along an edge

How do we decide whether a keypoint is poorly localized, say along an edge, vs. well-localized?

## 2. Keypoint Localization

— After keypoints are detected, we remove those that have **low contrast** or are **poorly localized** along an edge

How do we decide whether a keypoint is poorly localized, say along an edge, vs. well-localized?

$$C = \begin{bmatrix} \sum_{p \in P} I_x I_x & \sum_{p \in P} I_x I_y \\ \sum_{p \in P} I_y I_x & \sum_{p \in P} I_y I_y \end{bmatrix}$$

## 2. Keypoint Localization

— After keypoints are detected, we remove those that have **low contrast** or are **poorly localized** along an edge

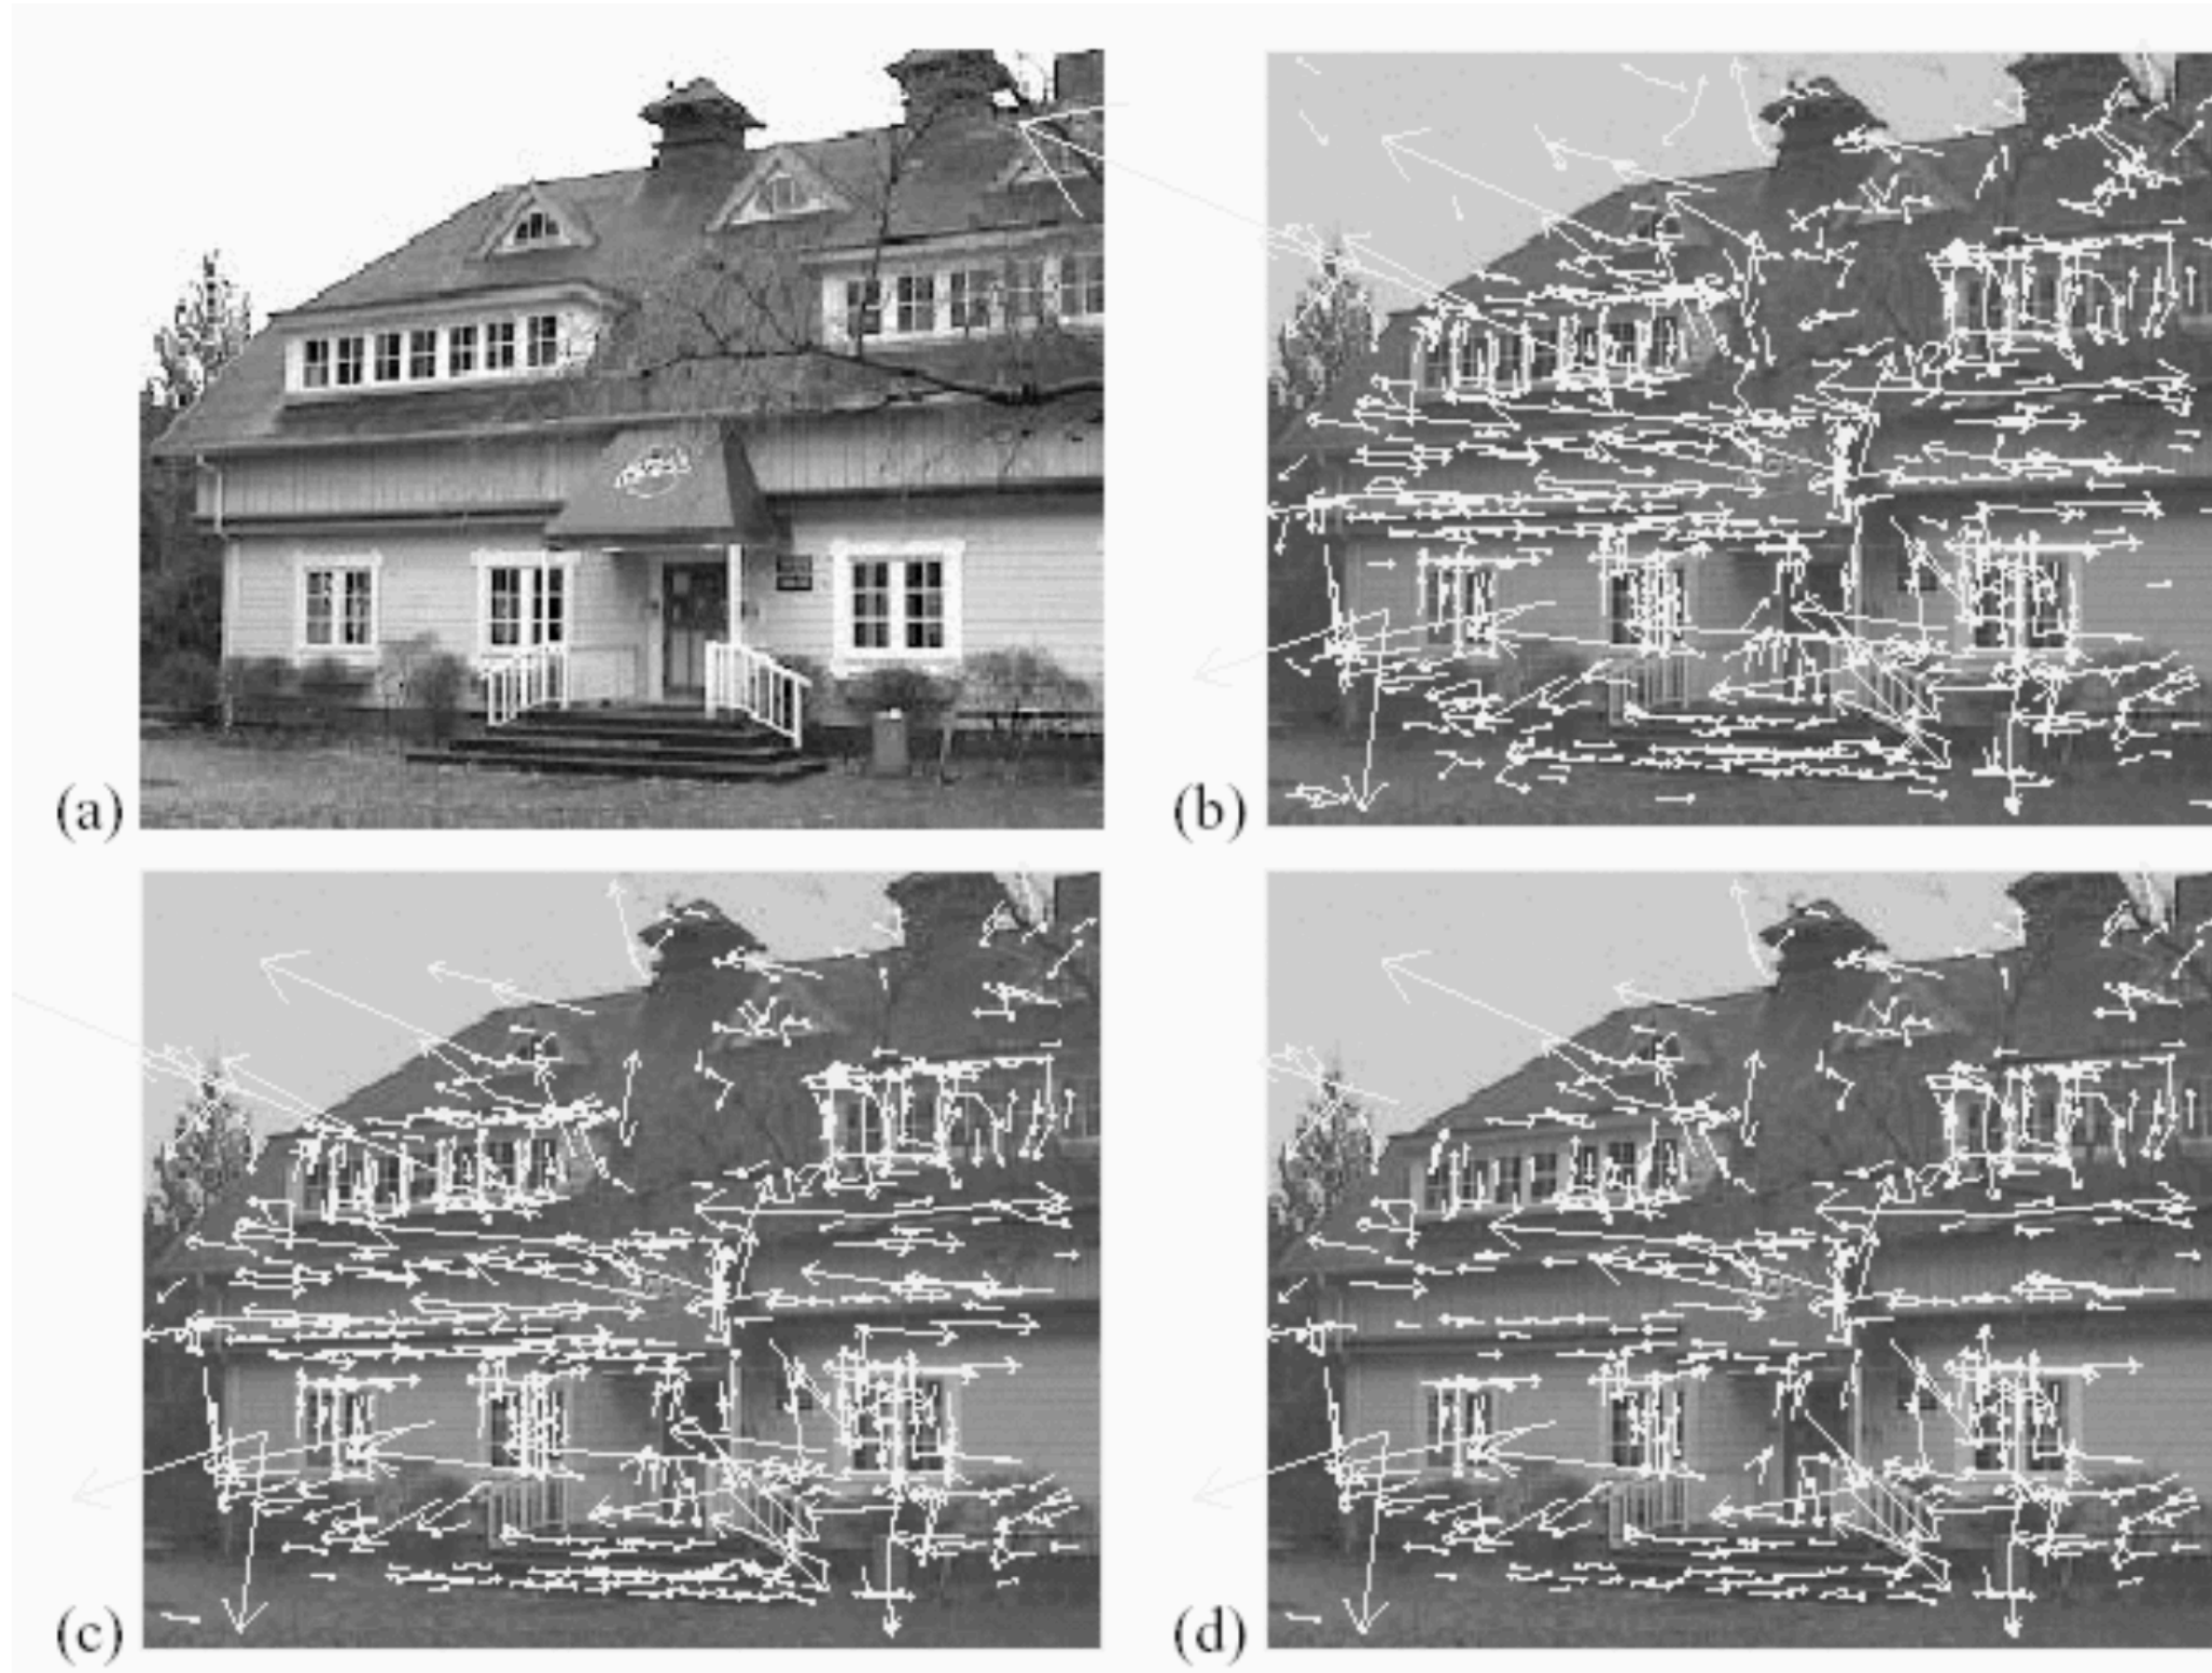

How do we decide whether a keypoint is poorly localized, say along an edge, vs. well-localized?

— Lowe suggests computing the ratio of the eigenvalues of  $\mathbf{C}$  (recall Harris corners) and checking if it is greater than a threshold

— Aside: The ratio can be computed efficiently in fewer than 20 floating point operations, using a trick involving the trace and determinant of  $\mathbf{C}$  - no need to explicitly compute the eigenvalues

## 2. Keypoint Localization

### Example:

(a)  $233 \times 189$   
image

(b) 832 DOG  
extrema

(c) 729 left after  
peak value  
threshold

(d) 536 left after  
testing ratio  
of principal  
curvatures

### 3. Orientation Assignment

- Create **histogram** of local gradient directions computed at selected scale
- Assign **canonical orientation** at peak of smoothed histogram
- Each key specifies stable 2D coordinates ( $x$  ,  $y$  , scale, orientation)

# 3. Orientation Assignment

Arrows illustrate **gradient orientation** (direction)  
and **gradient magnitude** (arrow length)

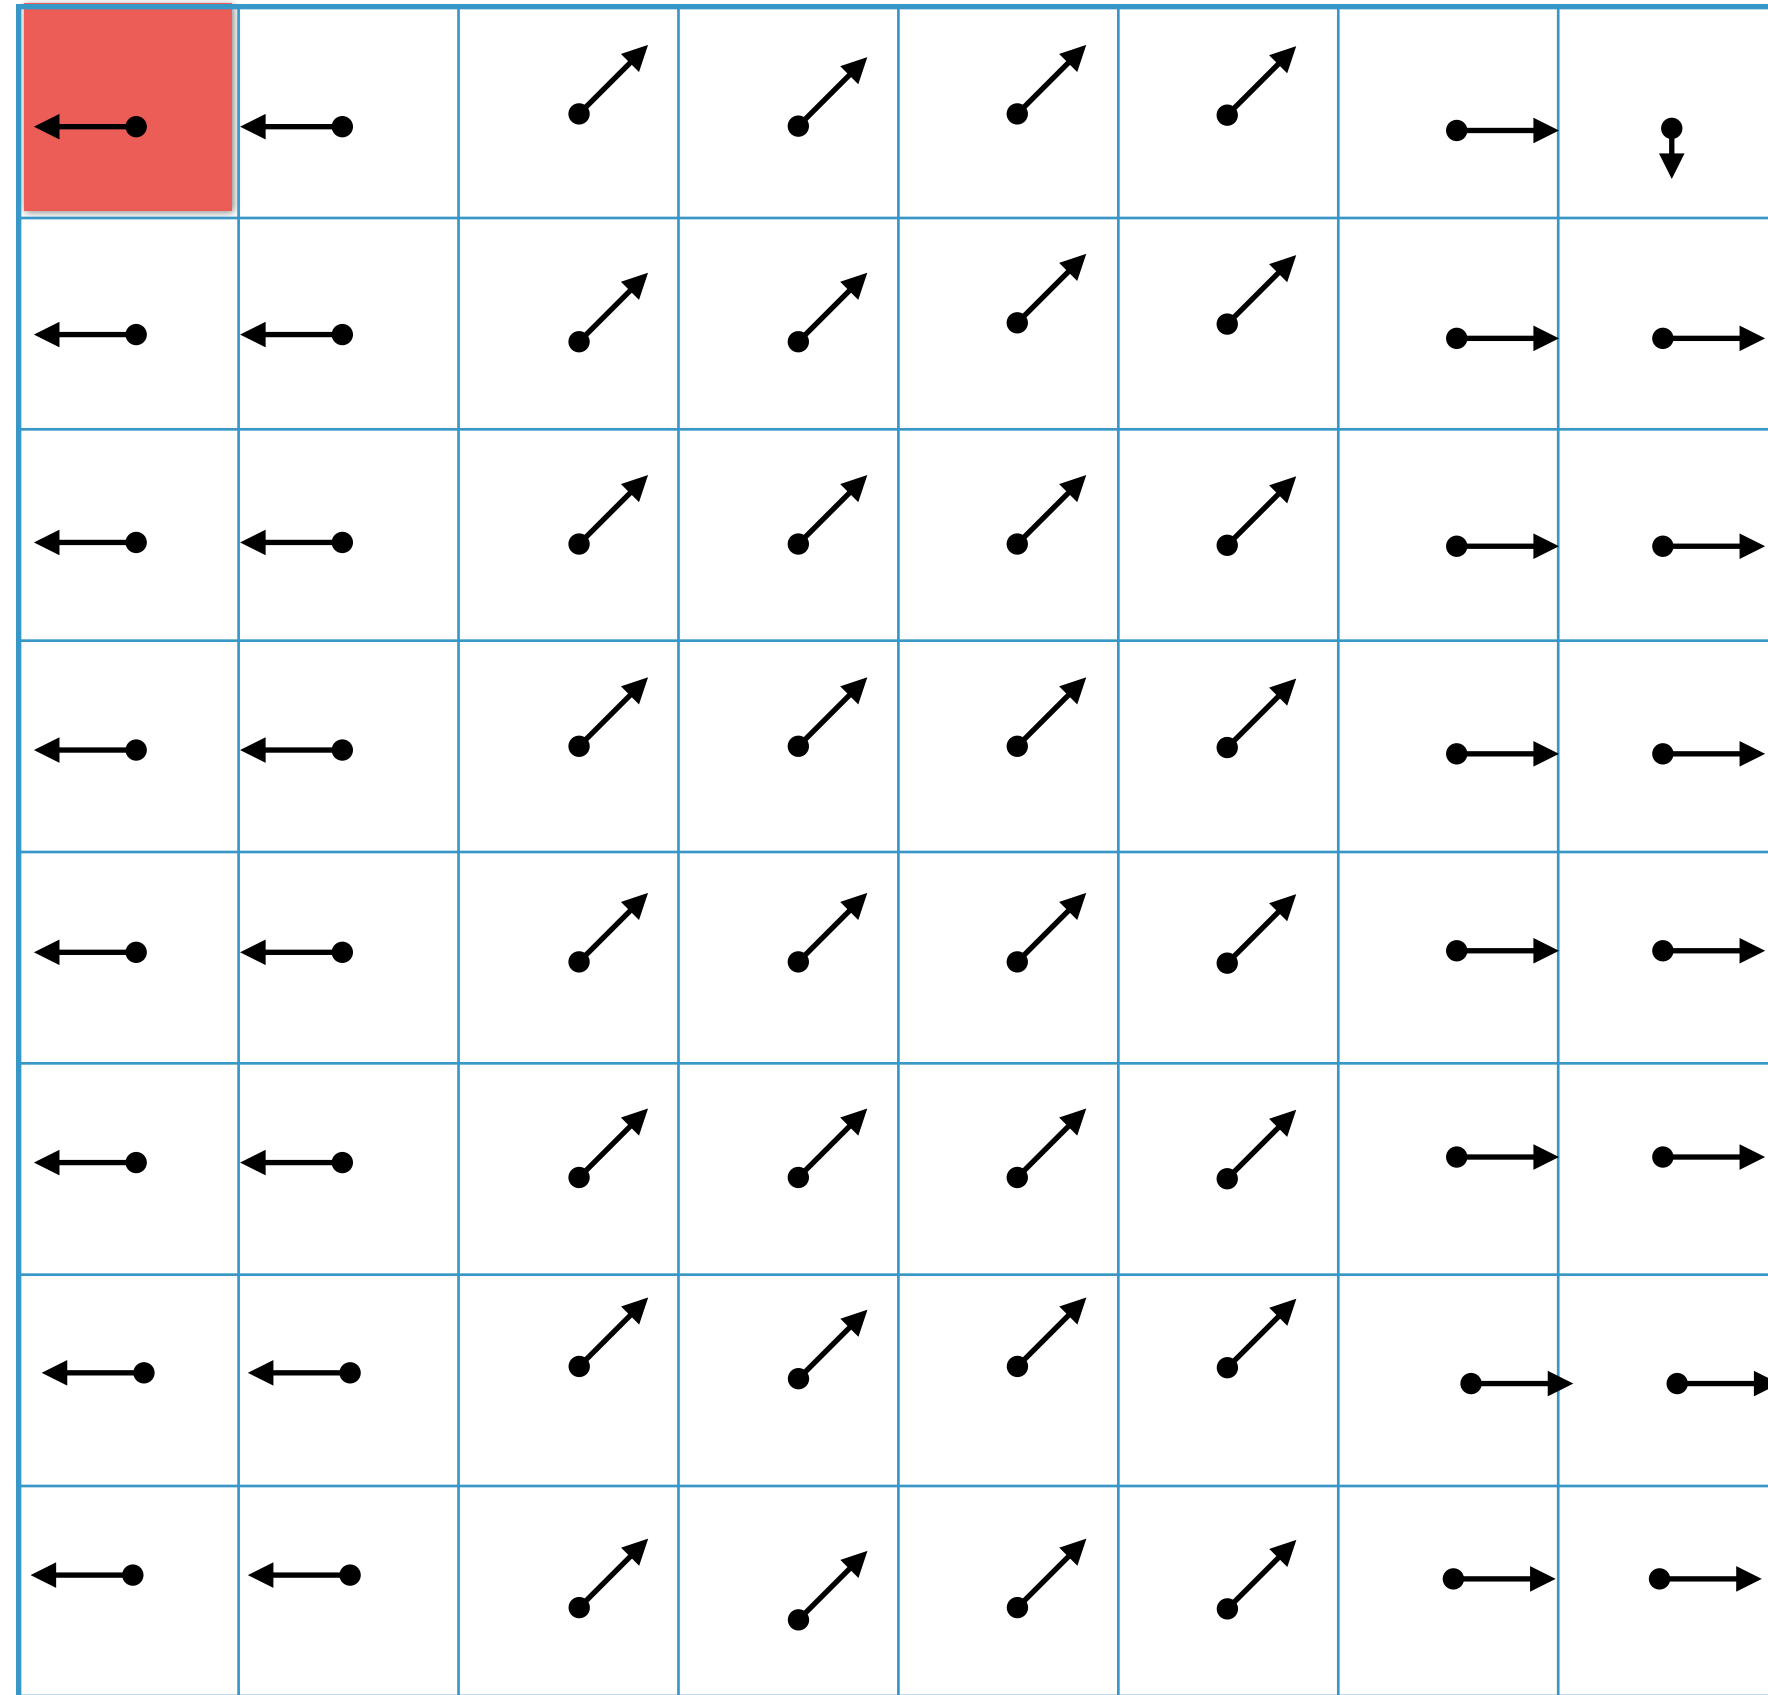

# 3. Orientation Assignment

Arrows illustrate **gradient orientation** (direction)  
and **gradient magnitude** (arrow length)

# 3. Orientation Assignment

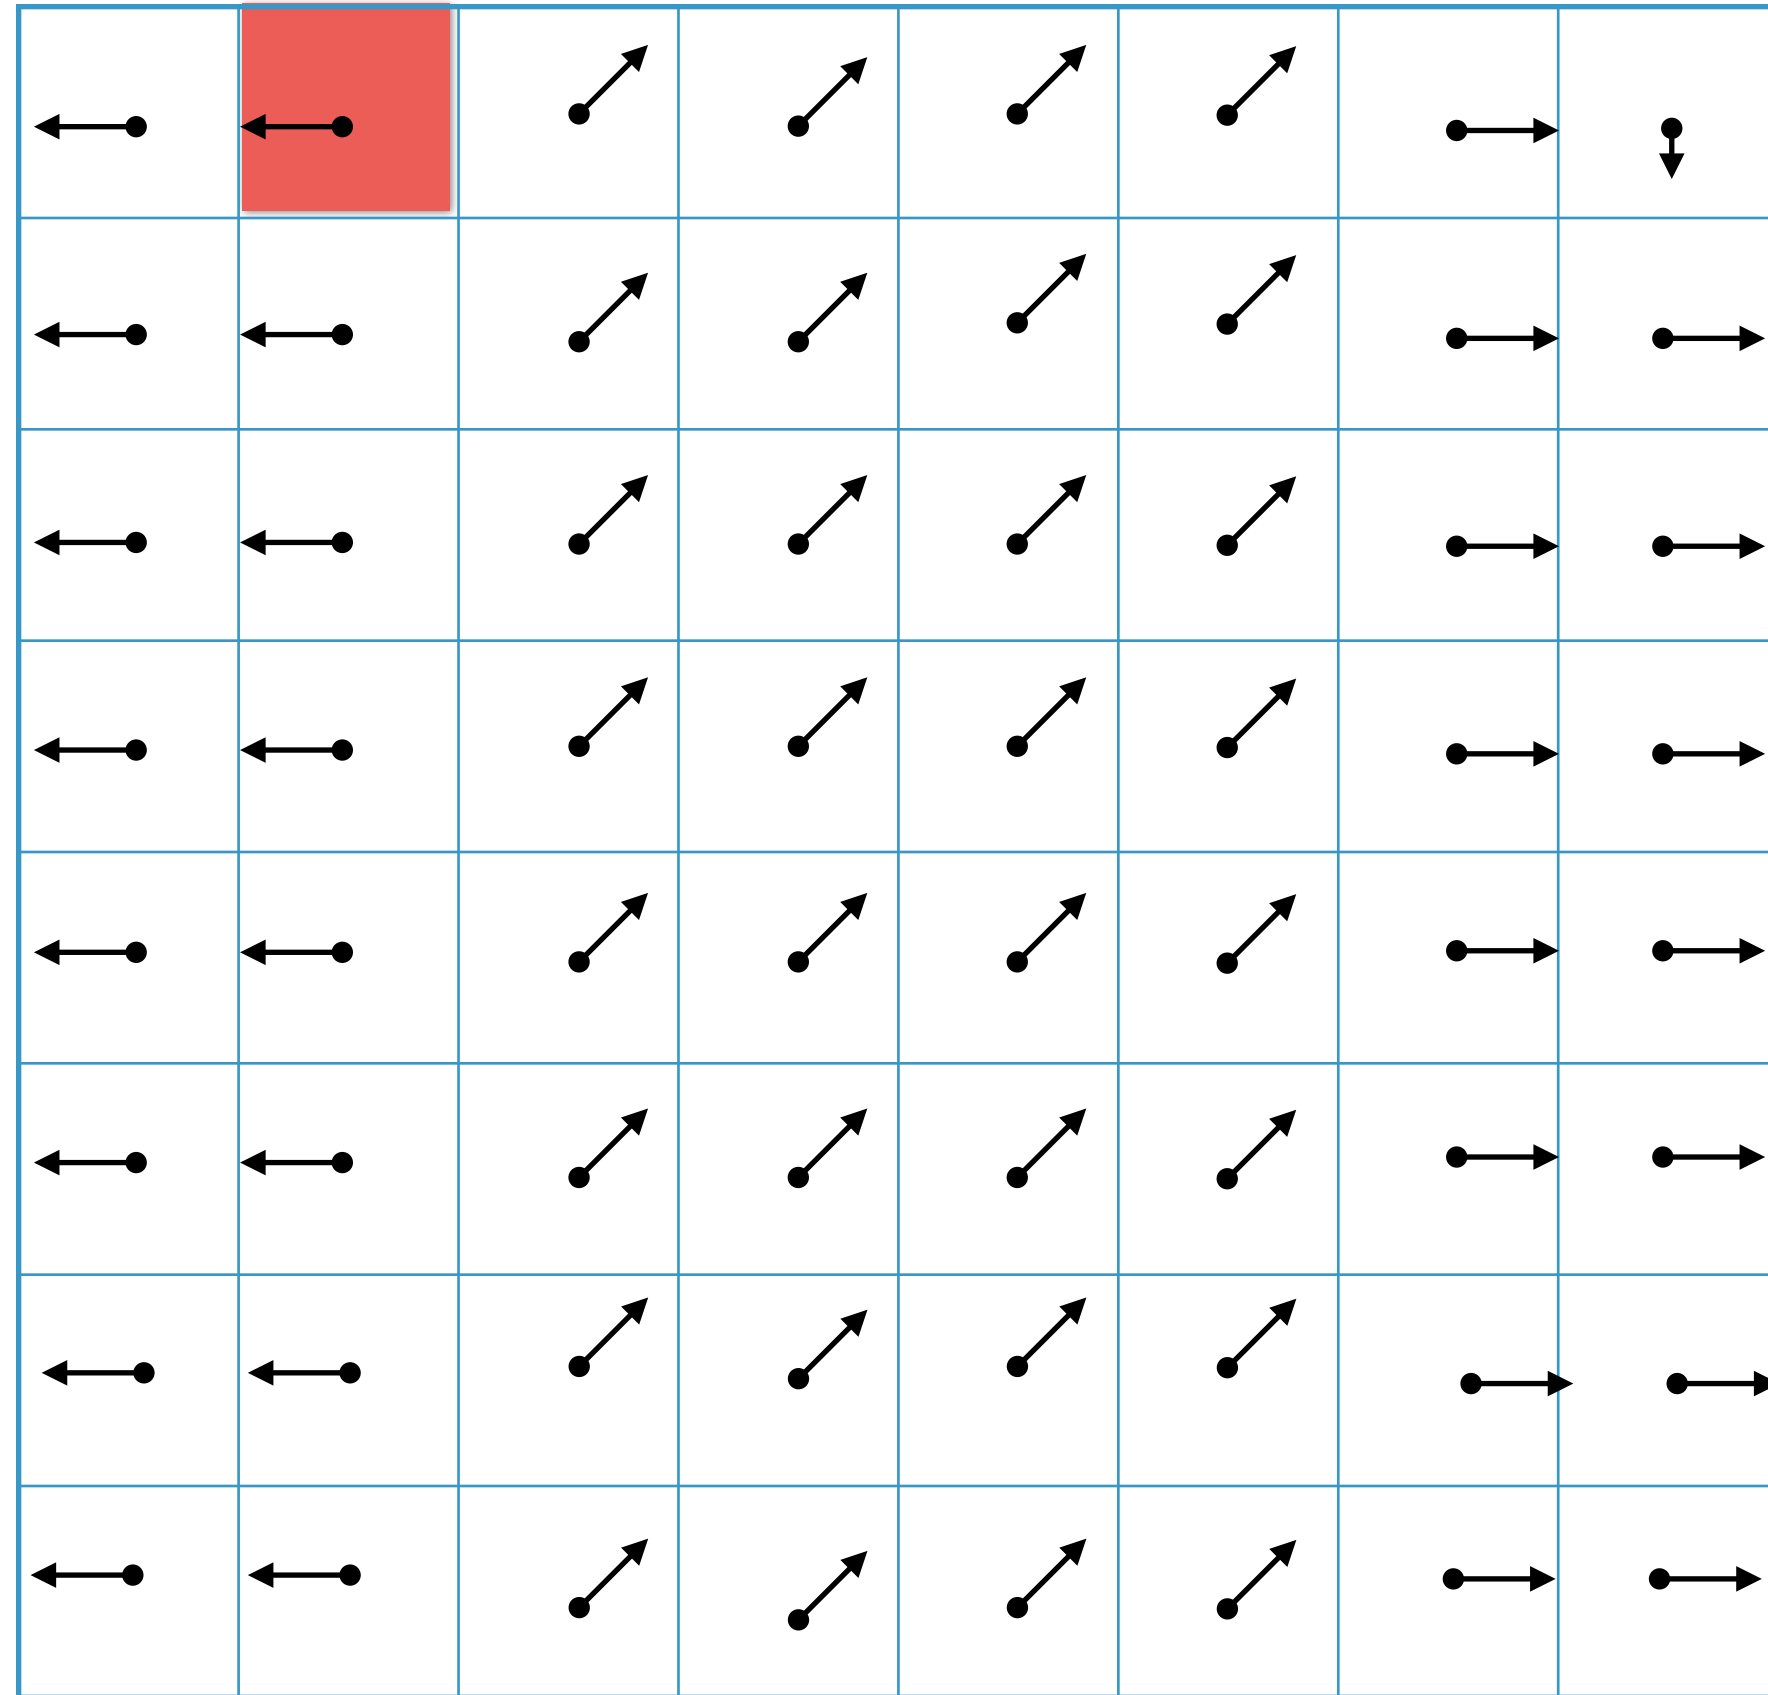

Arrows illustrate **gradient orientation** (direction) and **gradient magnitude** (arrow length)

# 3. Orientation Assignment

Arrows illustrate **gradient orientation** (direction) and **gradient magnitude** (arrow length)

# 3. Orientation Assignment

Arrows illustrate **gradient orientation** (direction) and **gradient magnitude** (arrow length)

# 3. Orientation Assignment

Arrows illustrate **gradient orientation** (direction) and **gradient magnitude** (arrow length)

# 3. Orientation Assignment

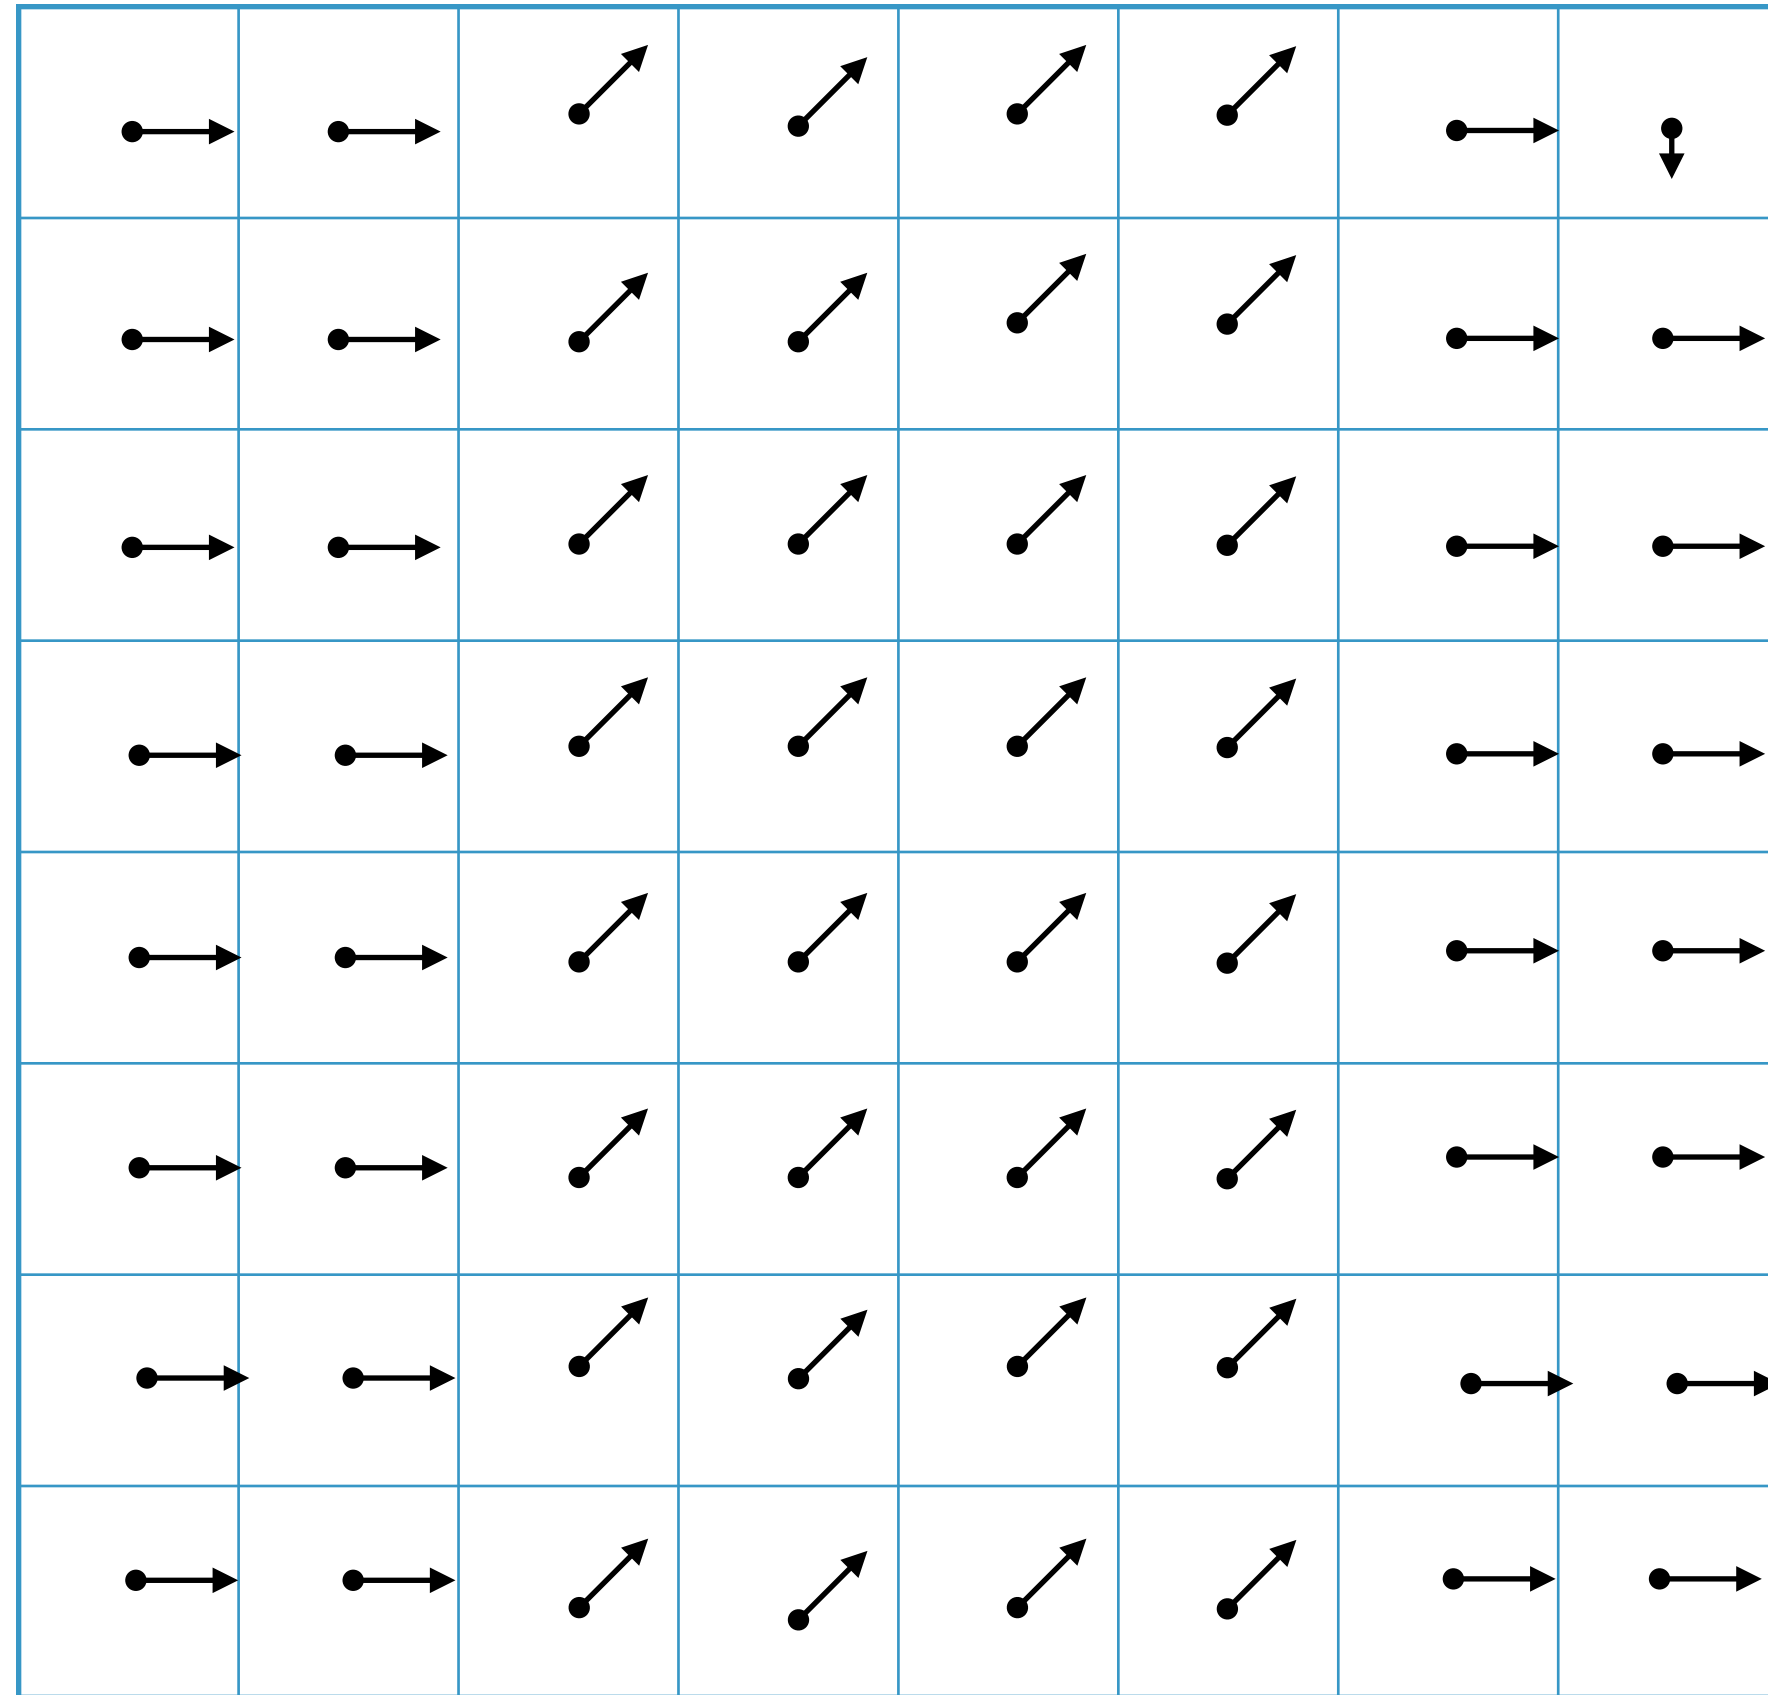

Arrows illustrate **gradient orientation** (direction) and **gradient magnitude** (arrow length)

# 3. Orientation Assignment

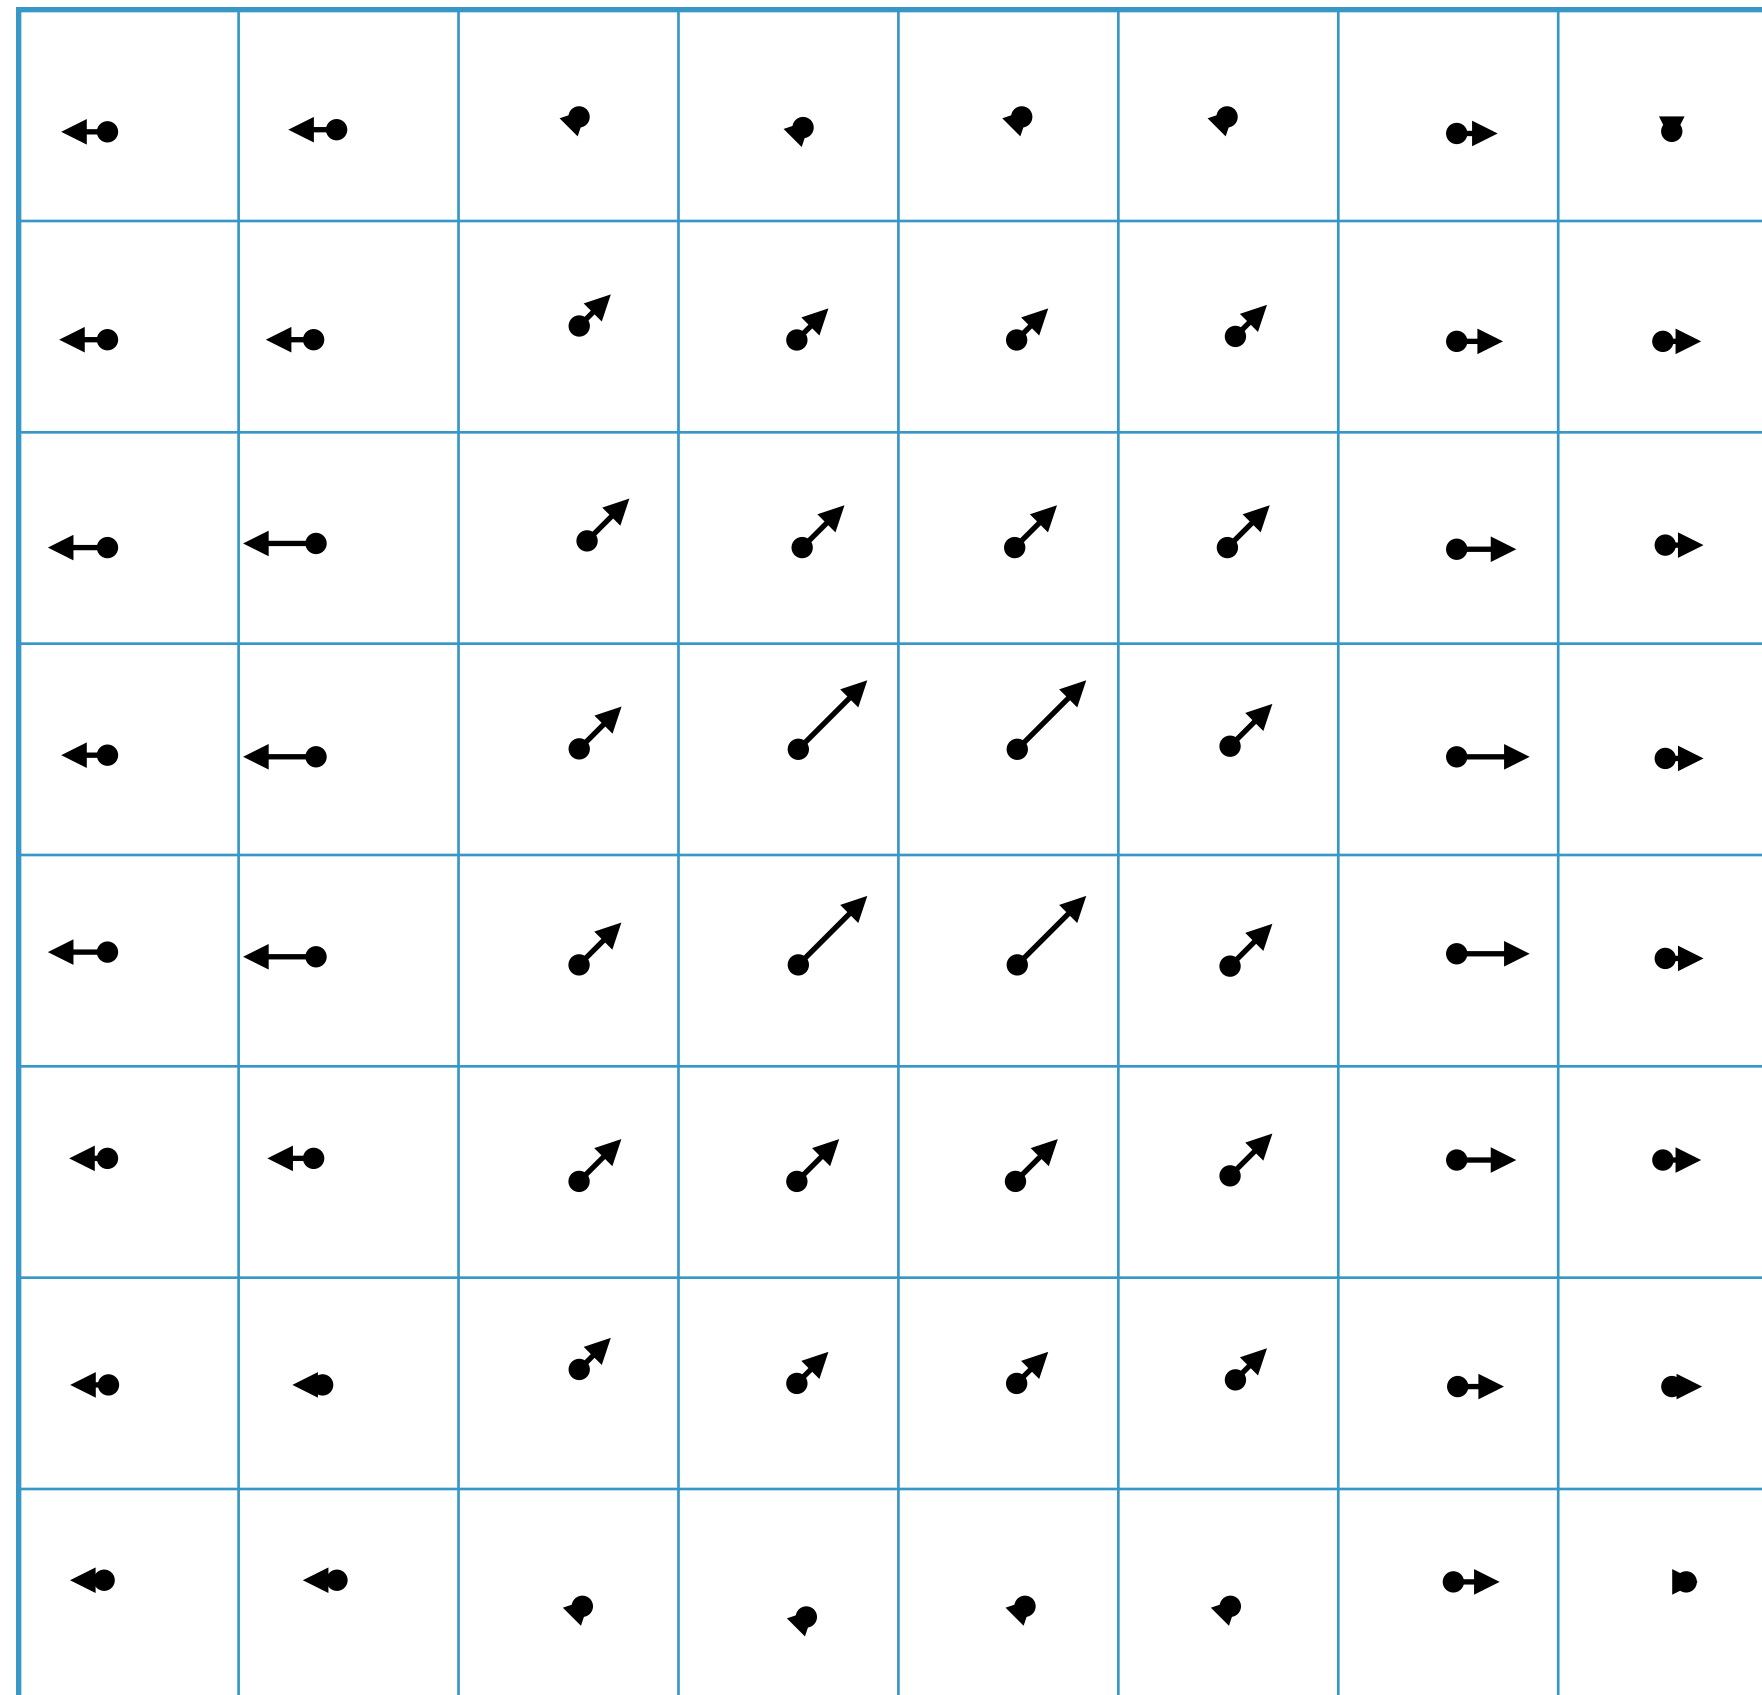

Arrows illustrate **gradient orientation** (direction) and **gradient magnitude** (arrow length)

# 3. Orientation Assignment

Multiply **gradient magnitude** by a **Gaussian** kernel

Arrows illustrate **gradient orientation** (direction) and **gradient magnitude** (arrow length)

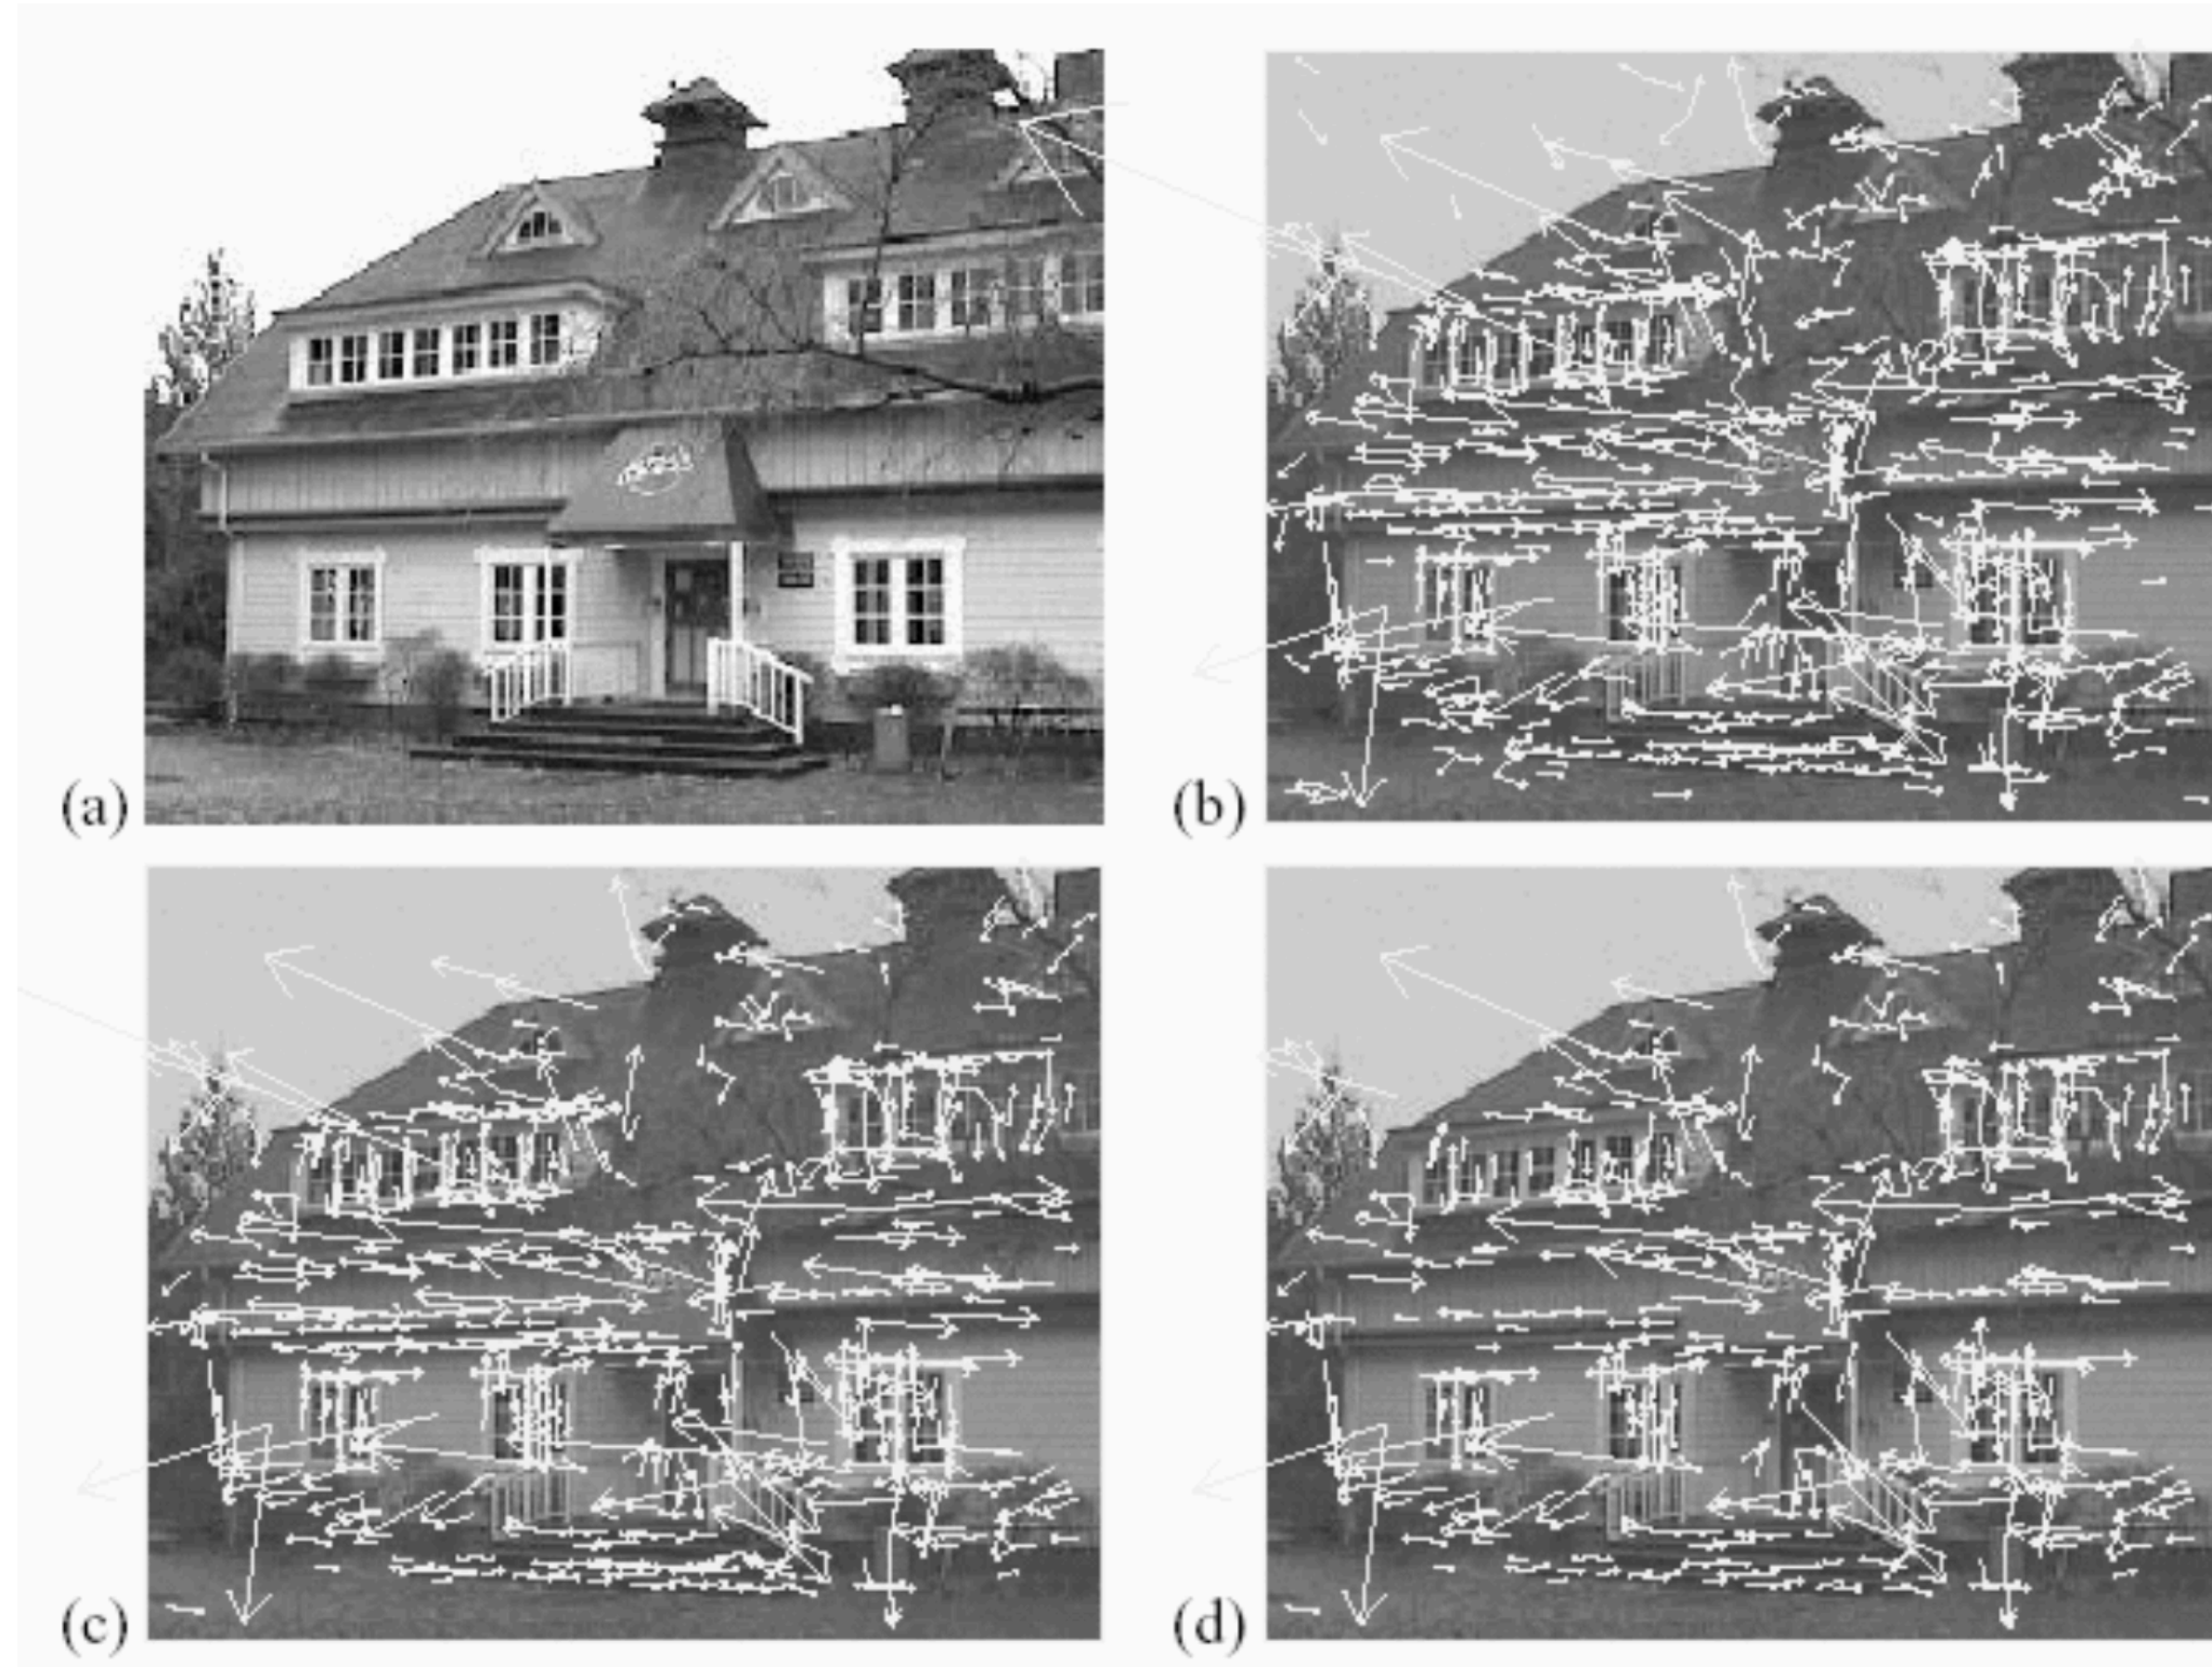

### 3. Orientation Assignment

- **Histogram** of 36 bins (10 degree increments)
- Size of the **window** is 1.5 scale (recall the Gaussian filter)
- Gaussian-weighted **voting**
- Highest **peak** and peaks above 80% of highest also considered for calculating dominant orientations

# 3. Keypoint Localization

## Example:

(a)  $233 \times 189$   
image

(b) 832 DOG  
extrema

(c) 729 left after  
peak value  
threshold

(d) 536 left after  
testing ratio  
of principal  
curvatures

# Scale Invariant Feature Transform (**SIFT**)

SIFT describes both a **detector** and **descriptor**

1. Multi-scale extrema detection
2. Keypoint localization
3. Orientation assignment
4. Keypoint descriptor

## 4. Keypoint Description

We have seen how to assign a location, scale, and orientation to each key point

- **keypoint detection**

- The next step is to compute a **keypoint descriptor**: should be robust to local shape distortions, changes in illumination or 3D viewpoint

- Keypoint detection is not the same as keypoint description, e.g. some applications skip keypoint detection and extract SIFT descriptors on a regularly spaced grid

# 4. SIFT Descriptor

- Image gradients are sampled over  $16 \times 16$  array of locations in scale space (weighted by a Gaussian with sigma half the size of the window)
- Create array of orientation histograms
- 8 orientations  $\times 4 \times 4$  histogram array

Image gradients

Keypoint descriptor

# 4. SIFT Descriptor

How many dimensions are there in a SIFT descriptor?

(**Hint:** SIFT descriptor uses a 4 x 4 array of 8D histogram)

## 4. SIFT Descriptor — Photometric Invariance

Descriptor is **normalized** to unit length (i.e. magnitude of 1) to reduce the effects of illumination change

- if brightness values are **scaled (multiplied)** by a constant, the gradients are scaled by the same constant, and the normalization cancels the change
- if brightness values are **increased/decreased** by a constant (**additive**), the gradients do not change

# SIFT Recap

## **Detector:**

- Find points that are maxima in a DOG pyramid
- Compute local orientation from gradient histogram
- This establishes a local coordinate frame with scale/orientation

## **Descriptor:**

- Build histograms over gradient orientations (8 orientations, 4x4 grid)
- Normalise the final descriptor to reduce the effects of illumination change

# SIFT Matching

Extract features from the image ...

Each image might generate 100's or 1000's of SIFT descriptors

# SIFT Matching

**Goal:** Find all correspondences between a pair of images

**Means:** extract and match all SIFT descriptors from both images

# SIFT Matching

- Each SIFT feature is represented by 128-D vector (numbers)
- Feature matching becomes the task of finding the closest 128-D vector
- Nearest-neighbor matching:

$$NN(j) = \arg \min_i |\mathbf{x}_i - \mathbf{x}_j|, i \neq j$$

- This is expensive (linear time), but good approximation algorithms exist  
e.g., Best Bin First K-d Tree [Beis Lowe 1997], FLANN (Fast Library for Approximate Nearest Neighbours) [Muja Lowe 2009]

# Match **Ratio Test**

Compare ratio of distance of **nearest** neighbour (1NN) to **second** nearest (2NN) neighbour — this will be a non-matching point

Rule of thumb:  $d(1NN) < 0.8 * d(2NN)$  for good match

# Feature Stability to **Noise**

Match features after random change in image scale & orientation, with differing levels of image noise

Find nearest neighbour in database of 30,000 features

# Feature Stability to **Affine Change**

Match features after random change in image scale & orientation, with differing levels of image noise

Find nearest neighbour in database of 30,000 features

# Summary

Four steps to SIFT feature generation:

## 1. **Scale-space representation and local extrema detection**

- use DoG pyramid
- 3 scales/octave, down-sample by factor of 2 each octave

## 2. **Keypoint localization**

- select stable keypoints (threshold on magnitude of extremum, ratio of principal curvatures)

## 3. **Keypoint orientation assignment**

- based on histogram of local image gradient directions

## 4. **Keypoint descriptor**

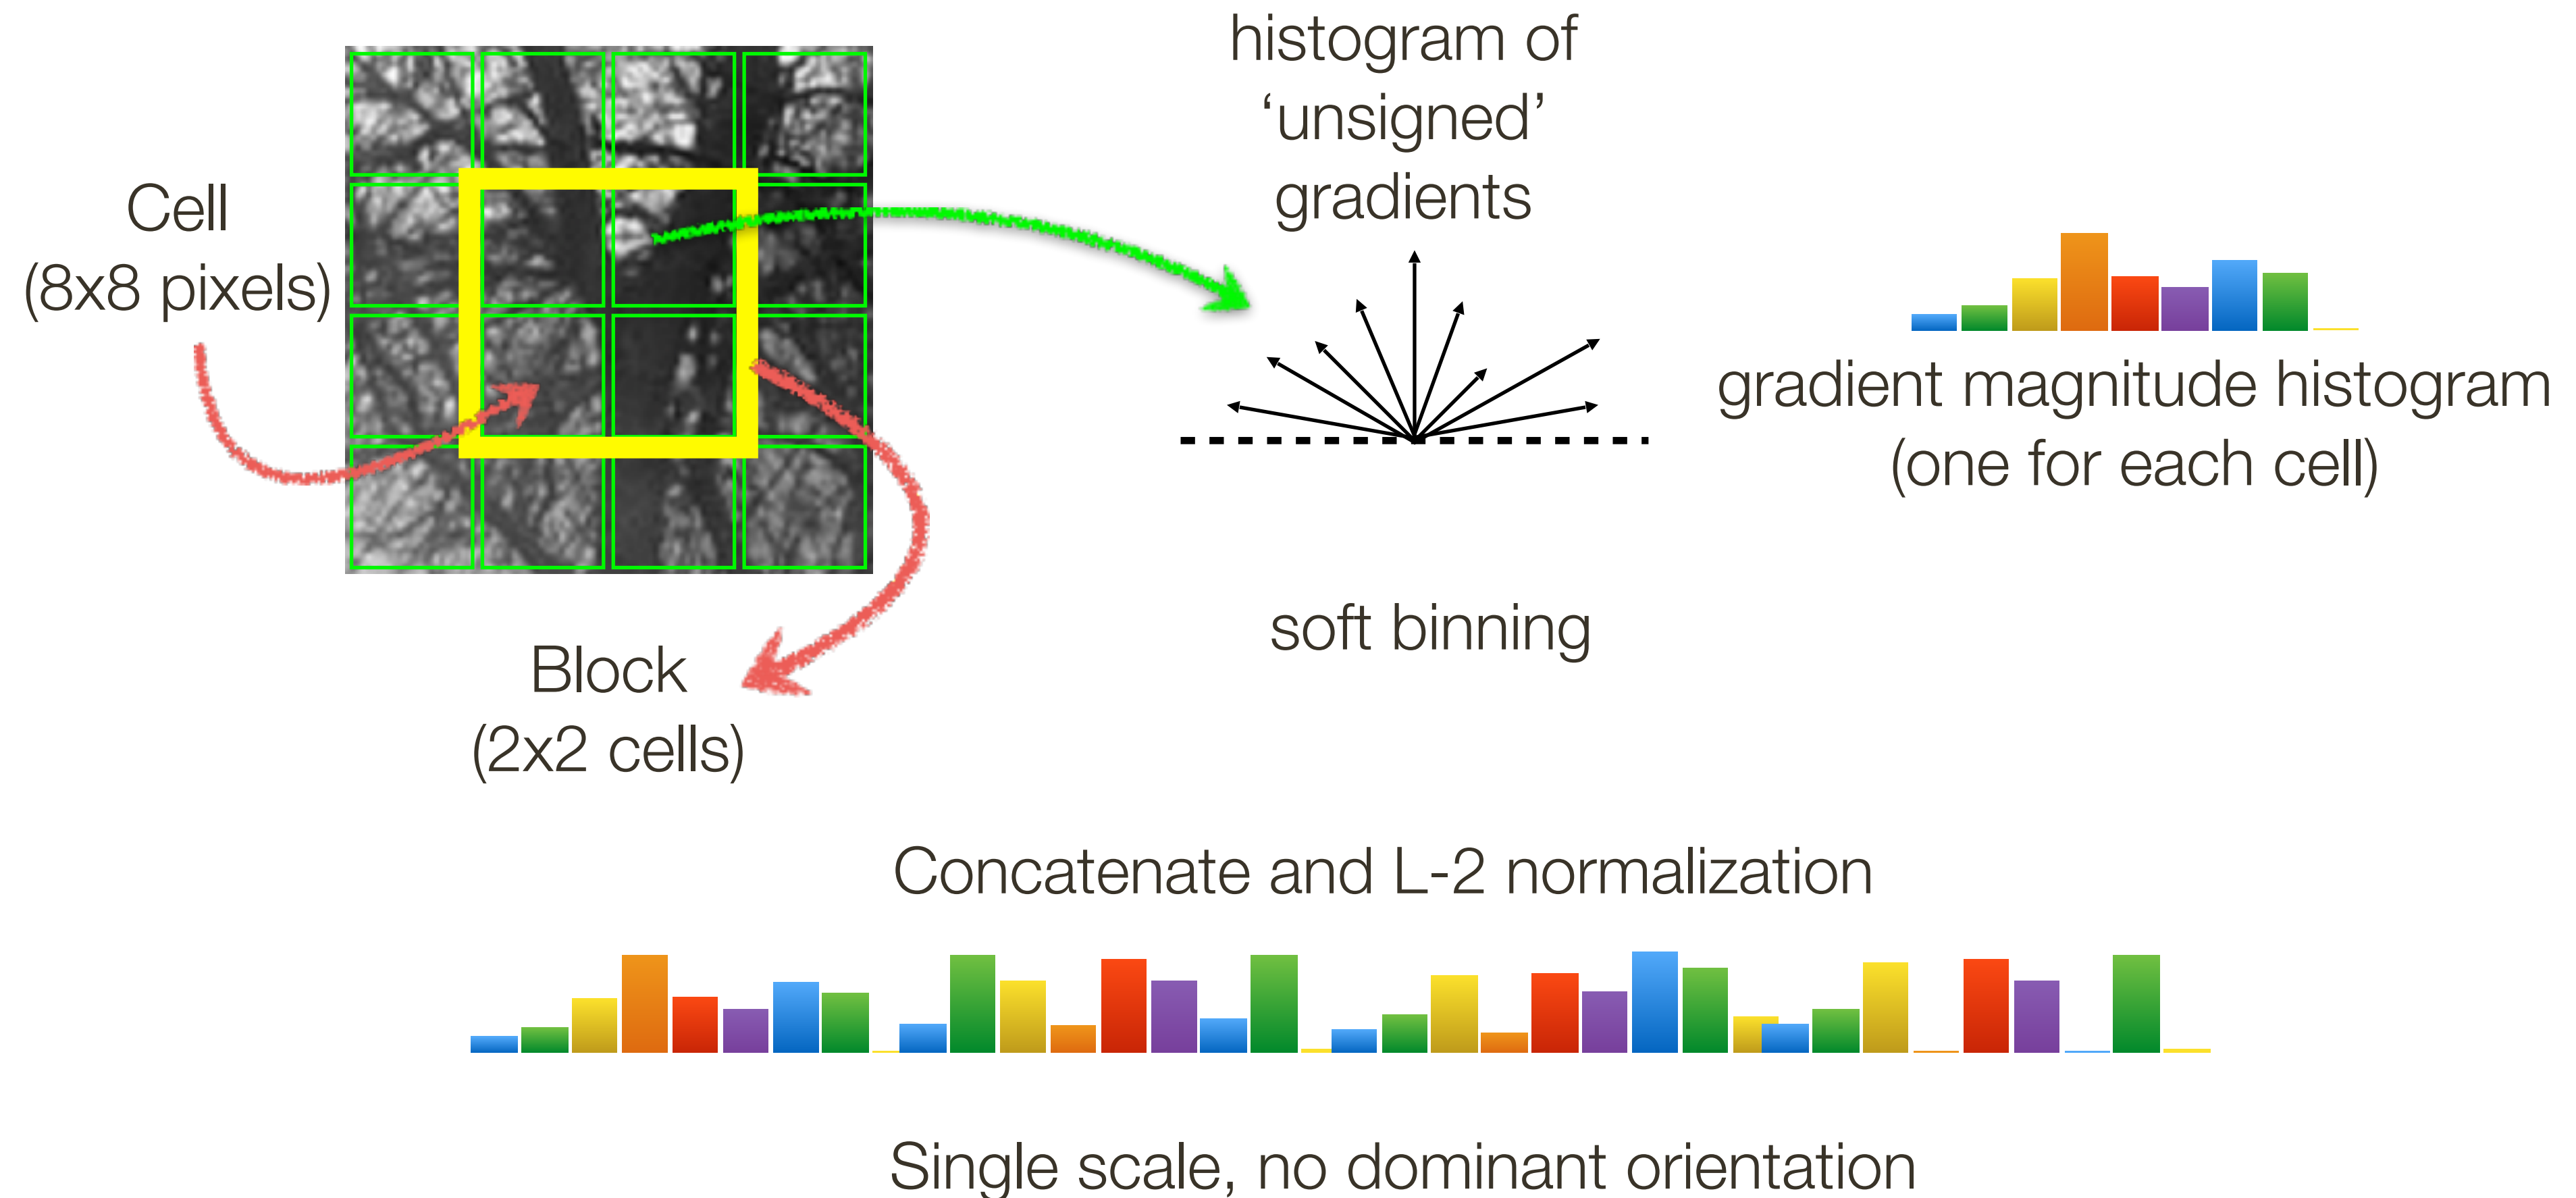

- histogram of local gradient directions — vector with  $8 \times (4 \times 4) = 128$  dim
- vector normalized (to unit length)
