# CPSC 340: Machine Learning and Data Mining

Decision Trees Summer 2021

**REMINDER TO HIT RECORD** 

# Admin

- Lecture 3: I need extra 5 minutes to catch up
  - I will improve my time management
- Assignment 1 is due Monday: start early.
  - Gradescope setup is still in progress
- Waiting list people: Start on A1!!
- Course webpage: <a href="https://www.cs.ubc.ca/~nhgk/courses/cpsc340s21/">https://www.cs.ubc.ca/~nhgk/courses/cpsc340s21/</a>
- Sign up for Piazza: <a href="https://piazza.com/ubc.ca/summer2021/cpsc340911">https://piazza.com/ubc.ca/summer2021/cpsc340911</a>
- Attend tutorials and office hours!

# In this Lecture

- Visualizing Data (10 minutes)
- Supervised Learning Intro (10 minutes)
- Course Notation (10 minutes)
- Decision Trees (30 minutes)

# Visualization

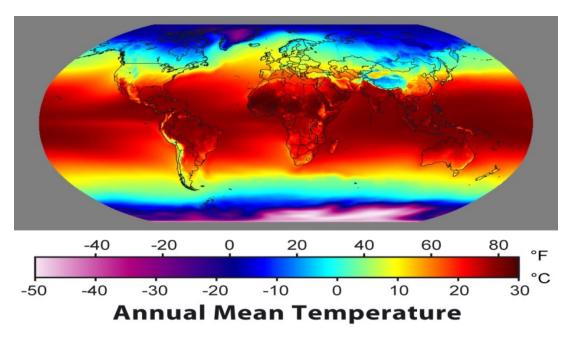

• You can learn a lot from 2D plots of the data:

VS.

– Patterns, trends, outliers, unusual patterns.

Lat	Long	Temp
0	0	30.1
0	1	29.8
0	2	29.9
Ο	3	30.1
Ο	4	29.9

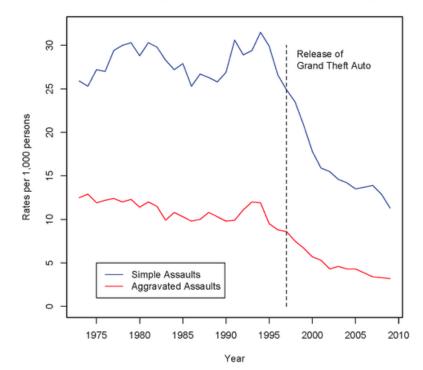

"Impenetrable sea of numbers" -Ted Kim

Intuitive visuals

# **Basic Plot**

• Visualize one variable as a function of another.

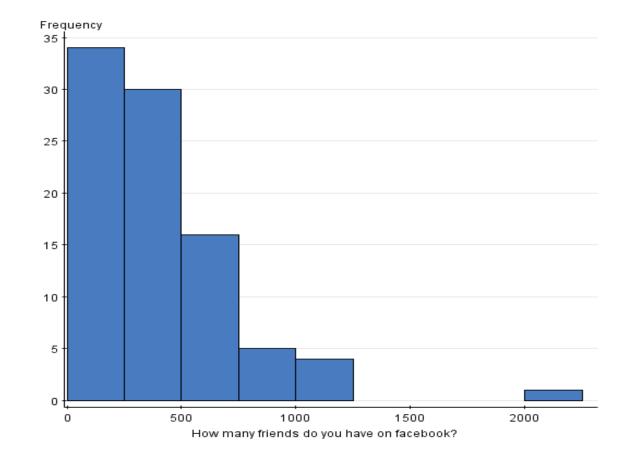

Assaults Reported in the BJS Victimization Survey

### • Fun with plots.

# Histogram

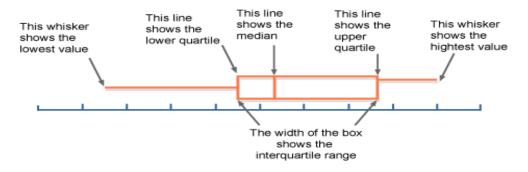

• Histograms display counts a variable, split into "bins".

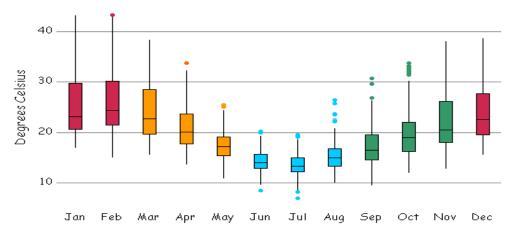

nttp://www.statcrunch.com/5.0/viewresult.php?resid=1

# **Box Plot**

Useful for visualizing summary statistics of multiple features in one view

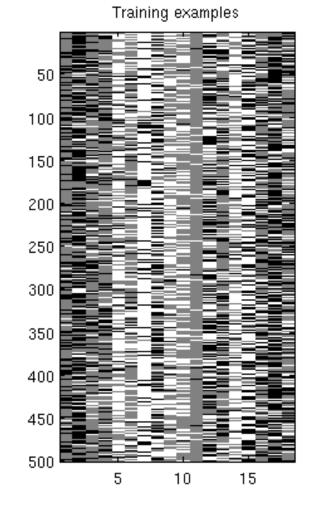

Maximum daily temperature in Melbourne

http://www.bbc.co.uk/schools/gcsebitesize/maths/statistics/representingdata3hirev6.shtml http://www.scc.ms.unimelb.edu.au/whatisstatistics/weather.html http://r.ramganalytics.com/r/facebook-likes-and-analytics/

# Matrix Plot

- We can view (examples) x (features) data table as a picture:
  - "Matrix plot".
  - May be able to see trends in features.

# **Correlation Plot**

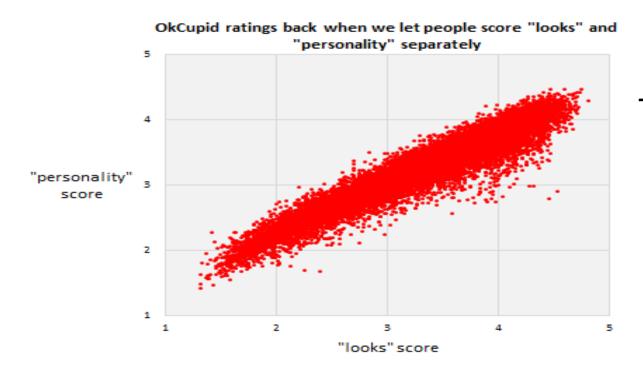

- A matrix plot of all similarities (or distances) between features:
  - Colour used to catch attention.

	BTC	ЕТН	XRP	XEM	ETC	LTC	DASH	XMR
BTC	1.00	0.61	0.36	0.51	0.60	0.56	0.55	0.66
ETH	0.61	1.00	0.28	0.49	0.68	0.43	0.70	0.64
XRP	0.36	0.28	1.00	0.48	0.08	0.35	0.40	0.44
XEM	0.51	0.49	0.48	1.00	0.40	0.43	0.47	0.52
ETC	0.60	0.68	0.08	0.40	1.00	0.47	0.56	0.53

https://www.crypto-news.net/portfolio-diversification-with-low-correlation-cryptos/

# Scatterplot

- Look at distribution of two features:
  - Feature 1 on x-axis.
  - Feature 2 on y-axis.

Shows correlation between
 "personality" score and
 "looks" score.

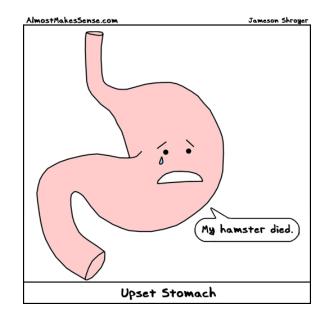

# "Why Not to Trust Plots"

- We've seen how summary statistics can be mis-leading.
- Note that plots can also be mis-leading, or can be used to mis-lead.
- Bonus slides: examples from UW's excellent course:
  - "Calling Bullshit in the Age of Big Data".
    - A course on how to recognize when people are trying to mis-lead you with data.
  - I recommend watching all the videos here:
    - <u>https://www.youtube.com/watch?v=A2OtU5vlR0k&list=PLPnZfvKlD1Sje5jWxt-4CSZD7bUl4gSPS</u>
  - Recognizing BS not only useful for data analysis, but for daily life.

# Coming Up Next SUPERVISED LEARNING

# Motivating Example: Food Allergies

You start getting an upset stomach frequently

• You suspect an adult-onset food allergy.

Q: How do I know which food made me sick?

# Motivating Example: Food Allergies

• To solve the mystery, you start a food journal:

Egg	Milk	Fish	Wheat	Shellfish	Peanuts	••••	Sick?
O	0.7	0	0.3	0	0		1
0.3	0.7	0	0.6	0	0.01		1
O	0	O	0.8	0	0		0
0.3	0.7	1.2	0	0.10	0.01		1
0.3	0	1.2	0.3	0.10	0.01		1

"Impenetrable sea of numbers"

-Ted Kim

- But it's hard to find the pattern!
  - You can't isolate and only eat one food at a time.
  - You may be allergic to more than one food.
  - The quantity matters: a small amount may be ok.
  - You may be allergic to specific interactions.

# Supervised Learning

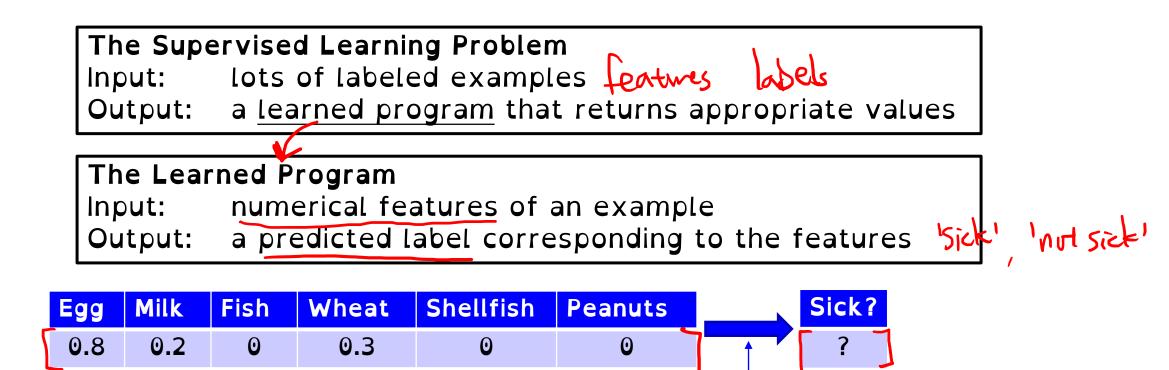

• We can formulate this as a supervised learning problem:

Egg	Milk	Fish	Wheat	Shellfish	Peanuts	•••	Sick?
0	0.7	0	0.3	O	0		1
0.3	0.7	0	0.6	0	0.01		1
0	O	O	0.8	0	0		0
0.3	0.7	1.2	0	0.10	0.01		1
0.3	O	1.2	0.3	0.10	0.01		1

- Goal of supervised learning:
  - Use data to find a model that outputs the right label based on the features.
  - Model predicts whether foods will make you sick (even with new combinations).

## Supervised Learning as Writing A Program

features

(aka "model" or "mapping")

label

The learned program

## Supervised Learning as Writing A Program

- Supervised learning is useful when you have lots of labeled data BUT:
  - 1. Problem is too complicated to write a program ourselves.
  - 2. Human expert can't explain why you assign certain labels.

#### OR

2. We don't have a human expert for the problem.

Try writing a self-driving car program by hand!!! (hint: it's impossible)

"Hey doctor, my FOXP3 gene looks like ATCGAGACGCGAGCCGCGACCACCGCGAGCGA. Does this mean I have a compromised immune system?"

# Supervised Learning

- This is the most successful machine learning technique:
  - Spam filtering, optical character recognition, Microsoft Kinect, speech recognition, classifying tumours, etc.
- We'll first focus on classification
  - learning with categorical labels
  - E.g. {'sick', 'not sick'}, {SF, New York}
- Here, the model is a called a "classifier".

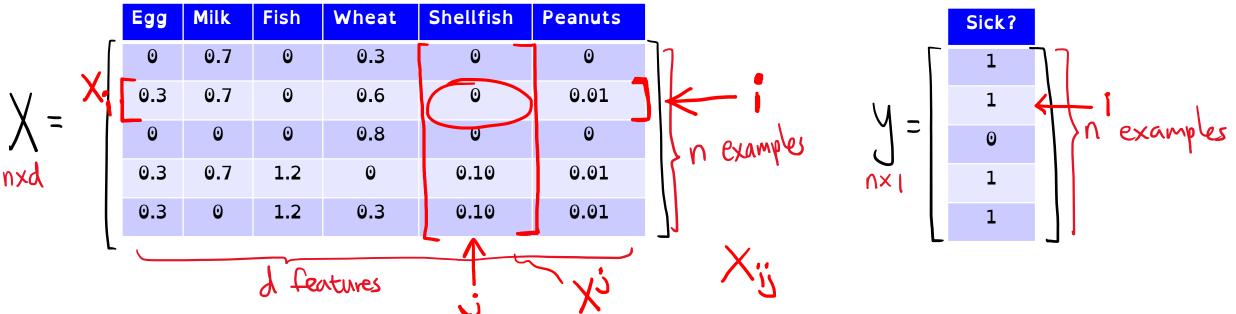

### Naïve Supervised Learning: "Return-the-Mode"

Egg	Milk	Fish	Wheat	Shellfish	Peanuts		Sick?
0	0.7	Ο	0.3	0	0		1
0.3	0.7	Ο	0.6	0	0.01		1
0	Ο	Ο	0.8	0	0		0
0.3	0.7	1.2	0	0.10	0.01		1
0.3	0	1.2	0.3	0.10	0.01		1

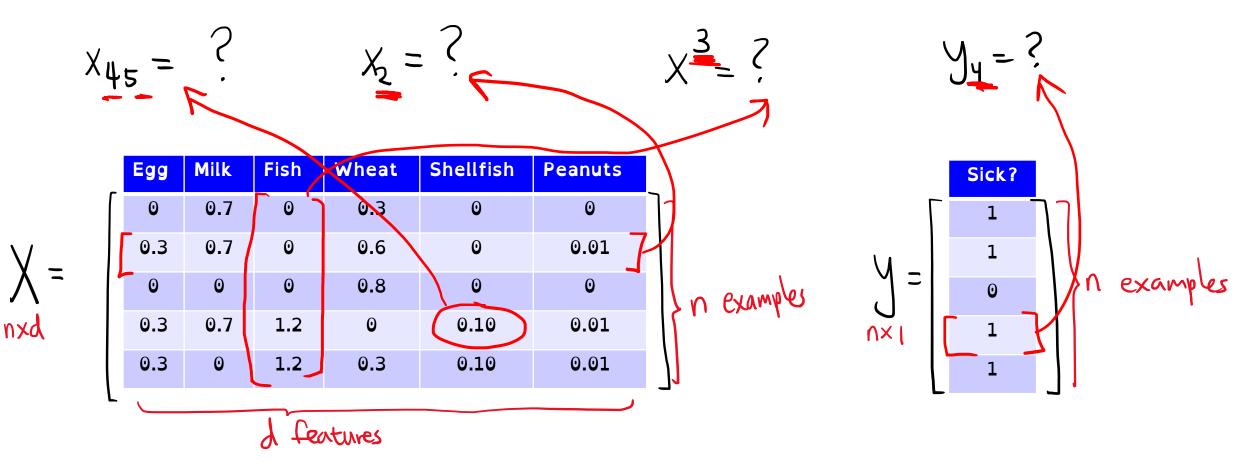

- A very naïve supervised learning method:
  - Always predict the most common label, the mode ("sick" above).
- This ignores the features!
  - cannot be more accurate than proportion of mode (80% in this case)
- We want to use the features, and there are MANY ways to do this.
  - We'll consider a classic way known as decision tree learning.

# Coming Up Next COURSE NOTATION

## Supervised Learning Notation (MEMORIZE THIS)

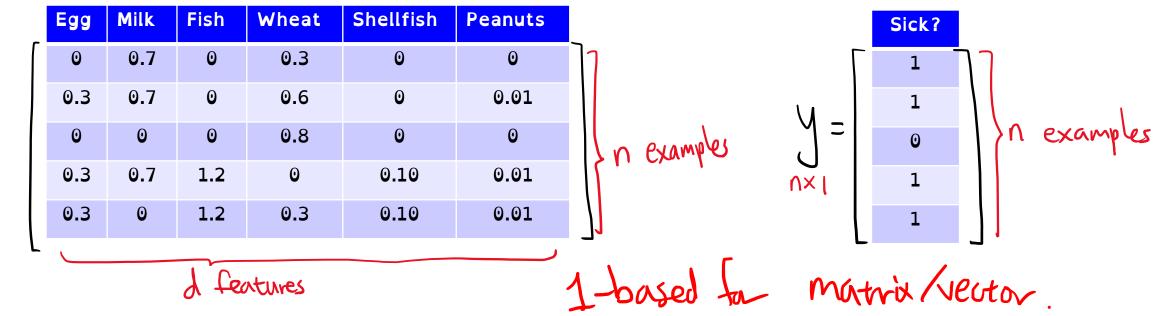

- Feature matrix 'X' has rows as examples, columns as features.
  - $x_{ij}$  is feature 'j' for example 'i' (quantity of food 'j' on day 'i').
  - $-x_i$  is the list of all features for example 'i' (all the quantities on day 'i').
  - $-x^{j}$  is column 'j' of the matrix (the value of feature 'j' across all examples).
- Label vector 'y' contains the labels of the examples.
  - $y_i$  is the label of example 'i' (1 for "sick", 0 for "not sick").

- Feature matrix 'X' has rows as examples, columns as features.
  - $x_{ij}$  is feature 'j' for example 'i' (quantity of food 'j' on day 'i').
  - $-x_i$  is the list of all features for example 'i' (all the quantities on day 'i').
  - $-x^{j}$  is column 'j' of the matrix (the value of feature 'j' across all examples).
- Label vector 'y' contains the labels of the examples.
  - $y_i$  is the label of example 'i' (1 for "sick", 0 for "not sick").

## Supervised Learning Notation (MEMORIZE THIS)

• Training phase:

nxd

- Use 'X' and 'y' to find a 'model' (a mapping of feature  $\rightarrow$  label)
- Prediction phase:
  - Given an example  $x_i$ , use 'model' to predict a label ' $\hat{y}_i$ ' ("sick" or "not sick").
- Training error:
  - Fraction of times our prediction  $\hat{y}_i$  does not equal the true  $y_i$  label.

z=Y

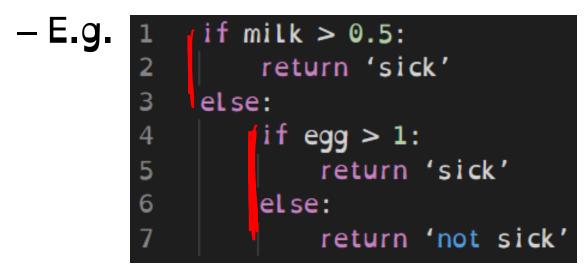

# Coming Up Next DECISION TREES

Hand-crafted decision tree at Starbucks (Agronomy Road)

# What is a Decision Tree?

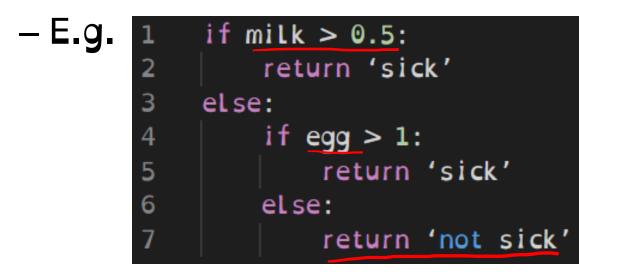

Nested if-else statements

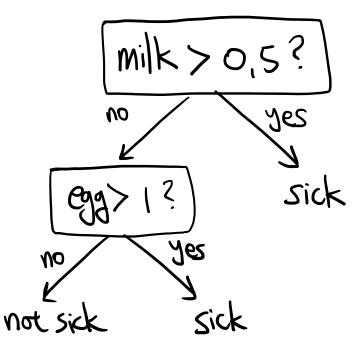

Q: How is this a "tree"?

# What is a Decision Tree?

Nested if-else statements

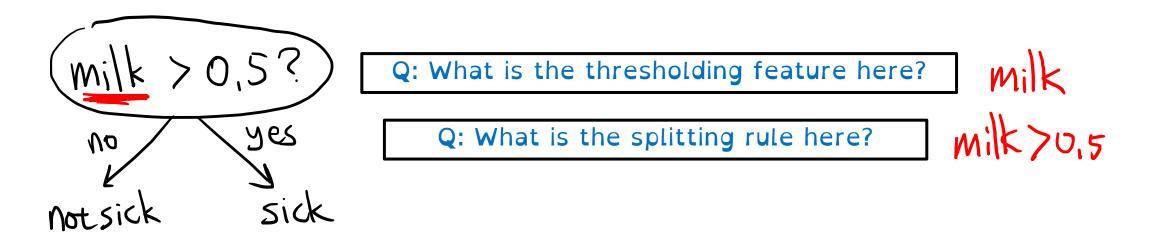

Q: According to this decision tree, what should we return for this example?

## Learning A Decision Stump: "Search and Score"

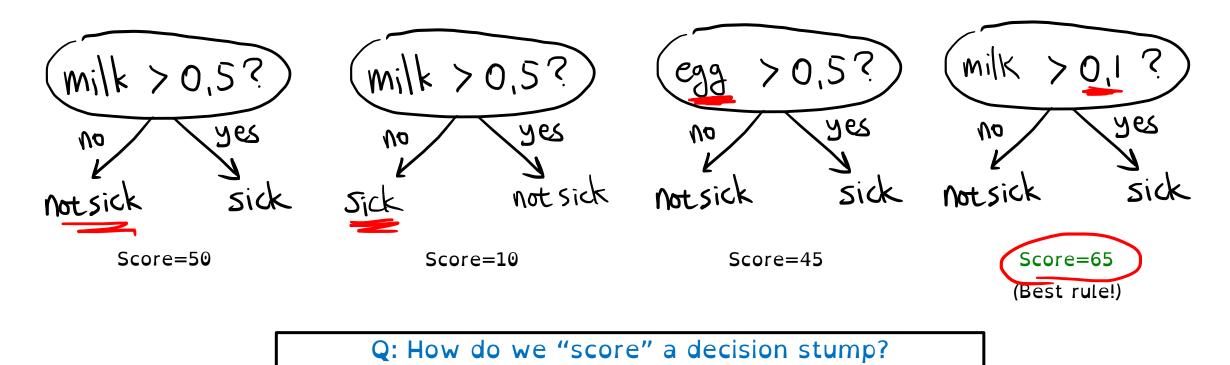

- We'll start with "decision stumps":
  - Simple decision tree with 1 splitting rule based on thresholding 1 feature.

Q: How do we find the best "rule" (feature, threshold, and leaf labels)?

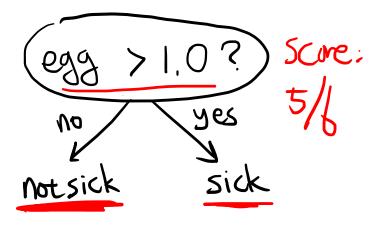

### Learning A Decision Stump: "Search and Score"

# Define a 'score' for the rule. Search for the rule with the best score.

## Learning A Decision Stump: Accuracy Score

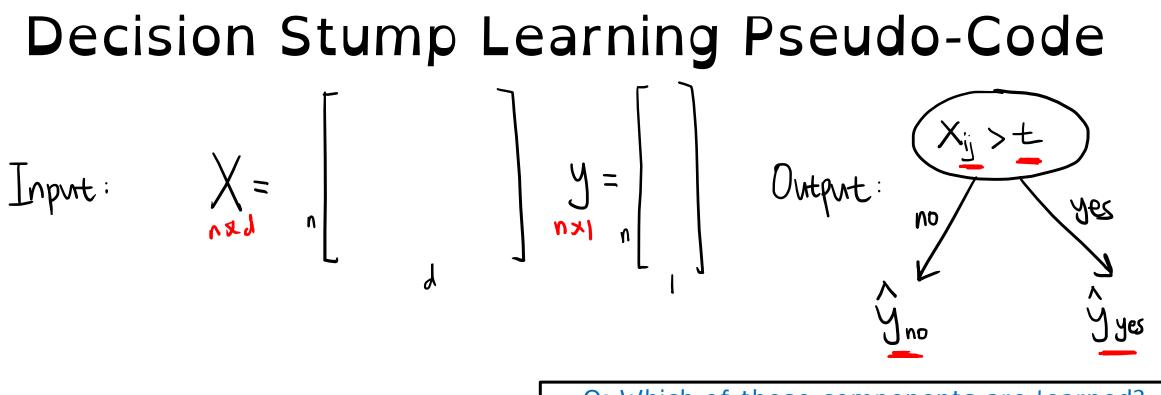

- Most intuitive score: classification accuracy.
  - "If we use this rule, how many examples do we label correctly?"

Milk	Fish	Egg		Sic
0.7	O	1		-
0.7	0	2 ←	•	
0	0	0		
0.7	1.2	0		
0	1.2	2 <	_	
0	0	0		

- Computing classification accuracy for this stump:
  - Find most common labels after applying splitting rule:
    - When (egg > 1), we were "sick" <u>2times out of</u>
    - When (egg  $\leq$  1), we were "not sick"  $\frac{3}{2}$  times out of  $\frac{4}{2}$ .
  - Compute accuracy:
    - The accuracy ("score") of the rule (egg > 1) is  $\frac{5}{2}$  times out of  $\frac{1}{2}$ .
- This "score" evaluates quality of a rule.
  - We "learn" a decision stump by finding the rule with the best score.

0

Q: Which of these components are <u>learned</u>?

### **Decision Stump Learning Pseudo-Code** y = Output: Input: yes ND / yes Search-and-Score ① enumerate ALL combinations of {j, t} (2) $X^{j} = \prod_{n \in I} \frac{X_{ij} > t}{1 \longrightarrow 1} \xrightarrow{X_{ij} > t} X^{j}_{yes} = \prod_{n \in I} \frac{X_{ij} > t}{1 \longrightarrow 1} \xrightarrow{X_{ij} > t} X^{j}_{yes} = \prod_{n \in I} \frac{X_{ij} > t}{1 \longrightarrow 1} \xrightarrow{X_{ij} > t} X^{j}_{yes} = \prod_{n \in I} \frac{X_{ij} > t}{1 \longrightarrow 1} \xrightarrow{X_{ij} > t} X^{j}_{no} = \prod_{n \in I} \frac{X_{ij} > t}{1 \longrightarrow 1} \xrightarrow{X_{ij} > t} X^{j}_{no}$ (3) Score, them all See post-lecture slides for more (3) score them all formal pseudo-code the one with best score! $\longrightarrow \{j', t', j'_{yes}, \}$ 33

# **Cost of Decision Stumps**

- How much does this cost?
- Assume we have:
  - 'n' examples (days that we measured).
  - 'd' features (foods that we measured).
  - 'k' thresholds (>0, >1, >2, ...) for each feature.
- Computing the score of one rule costs O(<u></u>):
  - We need to go through all 'n' examples to find modes for  $y_{yes}$  and  $y_{no}$ .
  - We need to go through all 'n' examples again to compute the accuracy.
  - See notes on webpage for review of "O(n)" notation.

### JEZ1,-, 03 te ミノ, っとろ

- We compute score for up to <u>k\*d</u> rules ('<u>k'</u> thresholds for each of '<u>d</u>' features):
  - So we need to do an O(n) operation k\*d times, giving total cost of O(n dk).

y D(n)

# Cost of Decision Stumps

(k := number of thresholds)

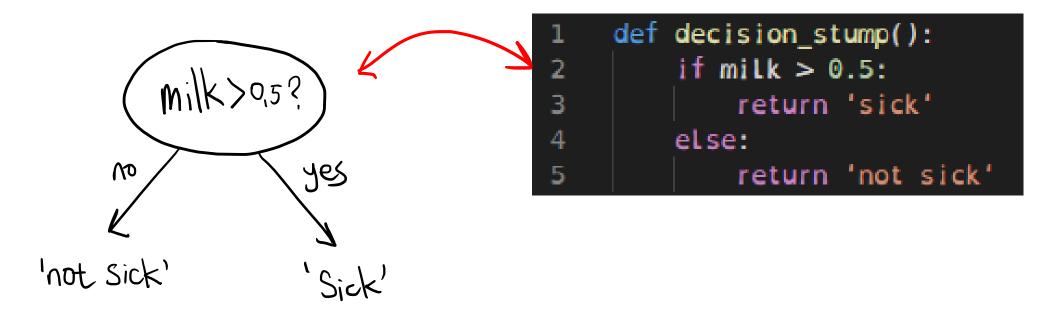

- Is a cost of O(ndk) good?
- Size of the input data is  $O(\underline{M} d)$ :
  - If 'k' is small then the cost is roughly the same cost as loading the data.

o(nd)+d(n)

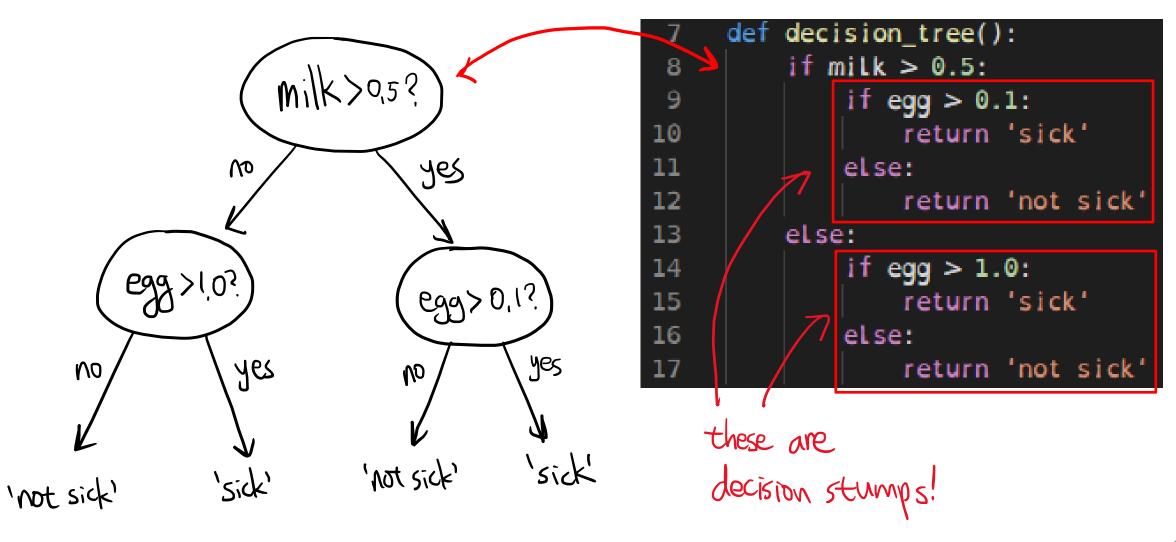

- We should be happy about this, you can learn on any dataset you can load!
- If 'k' is large then this could be too slow for large datasets.
- Example: if all our features are binary then k=1, just test (feature > 0):
   Cost of fitting decision stump is O(nd), so we can fit huge datasets.
- Example: if all our features are numerical with unique values then k=n.
  - Cost of fitting decision stump is  $O(\underline{n})$ .
    - Bad if 'n' is large!
  - Bonus slides: fitting decision stump in O(nd log n).
    Mol redel
    Basic idea: sort features and track labels.
    - Basic idea: sort features and track labels. Allows us to fit decision stumps to huge datasets.

# Coming Up Next DECISION STUMP TO DECISION TREE

### How Do I Make a Tree from Stumps?

### How Do I Make a Tree from Stumps?

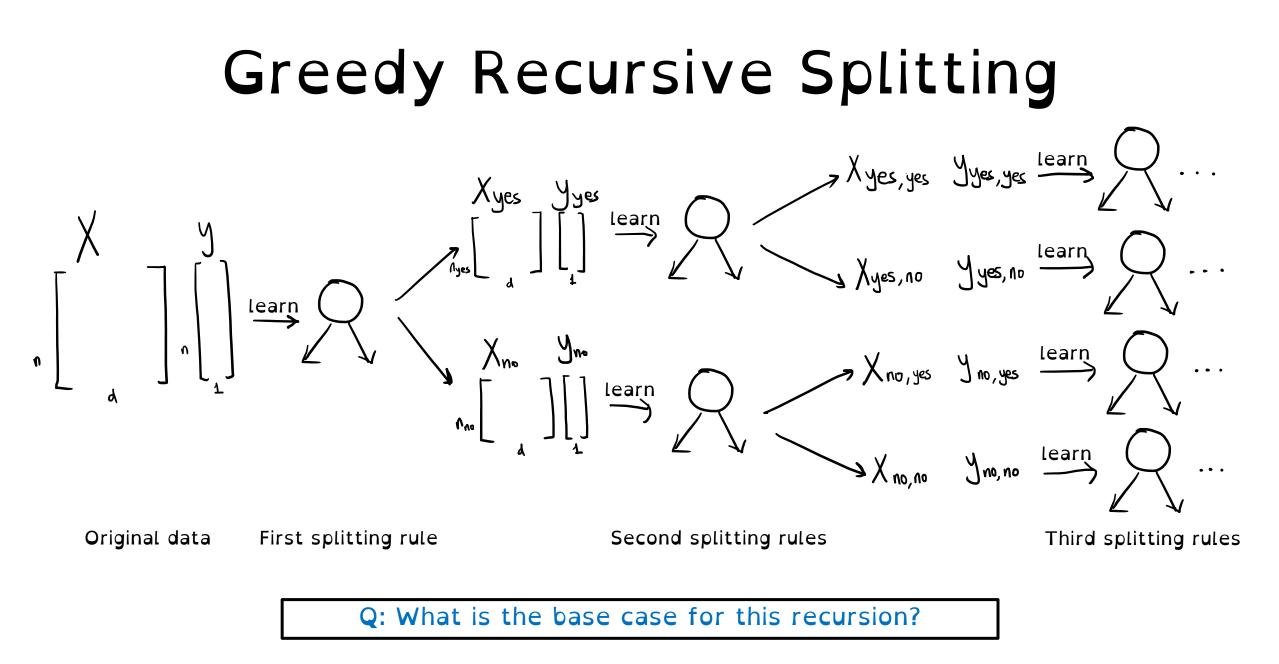

# **Decision Tree Learning**

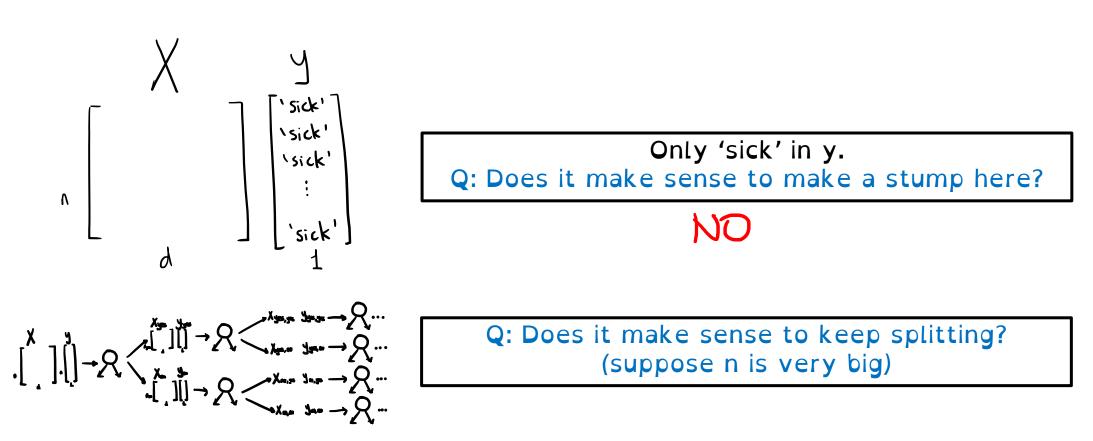

- Decision stumps have only 1 rule based on only 1 feature.
  - Very limited class of models: usually not very accurate for most tasks.
- Decision trees allow sequences of splits based on multiple features.
  - Very general class of models: can get very high accuracy.
  - However, it's computationally infeasible to find the best decision tree.
- Most common decision tree learning algorithm in practice:
  - Greedy recursive splitting.

NP-hard

# Stopping Criteria

When To Stop Greedy Recursive Splitting:
1. Only a single class remains in the labels
2. Maximum recursion depth reached
MSev-Jewel.

# A1 Skeleton Code

# Coming Up Next DISCUSSION ON DECISION TREES

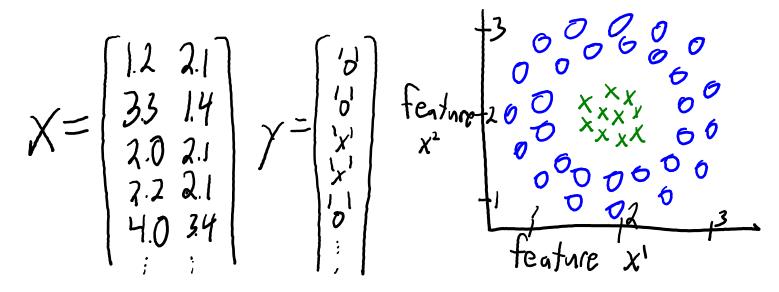

(freedy: locally optimal burd not recessarily globally optimal.

# Which score function should we use?

- What's wrong with using accuracy score with GRS? Greeky
  - Improving accuracy at level 1 doesn't mean you get best accuracy overall
- Sometimes we can't improve accuracy with a stump at all.
  - But this doesn't mean we should stop!

# Example Where Accuracy Fails

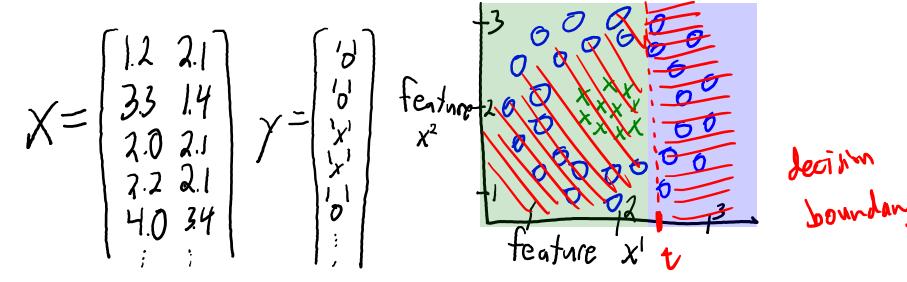

- Consider a dataset with 2 features and 2 classes ('x' and 'o').
  - Because there are 2 features, we can draw 'X' as a scatterplot.
    - Colours and shapes denote the class labels 'y'.

Q: How do we visualize a decision stump here?

# Example Where Accuracy Fails

- A decision stump would divide space by a horizontal or vertical line.
   E.g. , > t
- On this dataset, a horizontal/vertical line cannot do better than return-the-mode.

## Which score function should we use?

- Most common score in practice is "information gain".
  - Information gain := [entropy before split] [entropy after split]

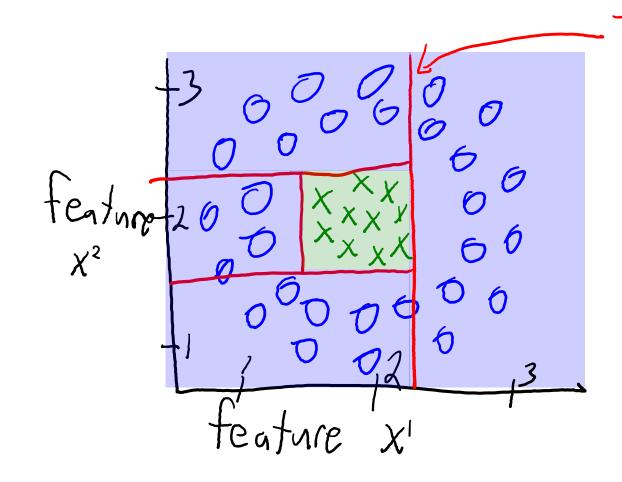

Q: When is information gain large?

- Information gain for baseline rule ("do nothing") is  $\underline{O}$ .
- · Infogain is largest if labels are <u>perfeuly split (e.g. you is all 'sick</u>.
- Less greedy than classification accuracy GRS
  - Even if accuracy isn't better with current stump, accuracy may increase with more depth.

# Example Where Accuracy Fails

This split makes labels less random. (Everything on the right is a 'o') It did not improve accuracy.

# Example Where Accuracy Fails

This split makes labels less random. (Everything on the right is a 'o') It did not improve accuracy. But three more splits maximizing intogain lead to perfect accuracy.

# **Discussion of Decision Tree Learning**

- Advantages:
  - Easy to implement.
  - Interpretable.
  - Learning is fast. Prediction is very fast.
- Disadvantages:
  - Hard to find optimal set of rules.
  - Greedy splitting often not accurate, requires very deep trees

# Discussion of Decision Tree Learning

#### Issues:

- Can you revisit a feature?
  - Yes, knowing other information could make feature relevant again.
- More complicated rules?
  - Yes, but searching for the best rule gets much more expensive.
- What is best scoring function?
  - Infogain is the most popular and often works well, but is not always the best.
- What if you get new data?
  - Consider splitting if there is enough data at the leaves, but occasionally might want to re-learn the whole tree or sub-trees.
- What depth?
  - Some implementations stop at a maximum depth, some stop if too few examples in leaf, some stop if infogain is too small.

# Summary

- Exploring data:
  - Data visualization
- Supervised Learning:
  - Using data to write a program based on input/output examples.
- Decision trees: predicting a label using a sequence of simple rules.
- **Decision stumps:** simple decision tree that is very fast to fit.
- Greedy recursive splitting: uses a sequence of stumps to fit a tree.
  - Very fast and interpretable, but not always the most accurate.
- Information gain: splitting score based on decreasing entropy.
- Next time: the most important ideas in machine learning.

# **Review Questions**

- Q1: Is "return-the-mode" always a bad idea? Why?
- Q2: What is the output of a supervised learning algorithm?
- Q3: What are the 4 parameters of a decision stump?
- Q4: In course notation, what are n, d, i, and j?
- Q5: Why is finding an optimal decision tree difficult?
- Q6: How many thresholds do we need to look at for a decision stump?

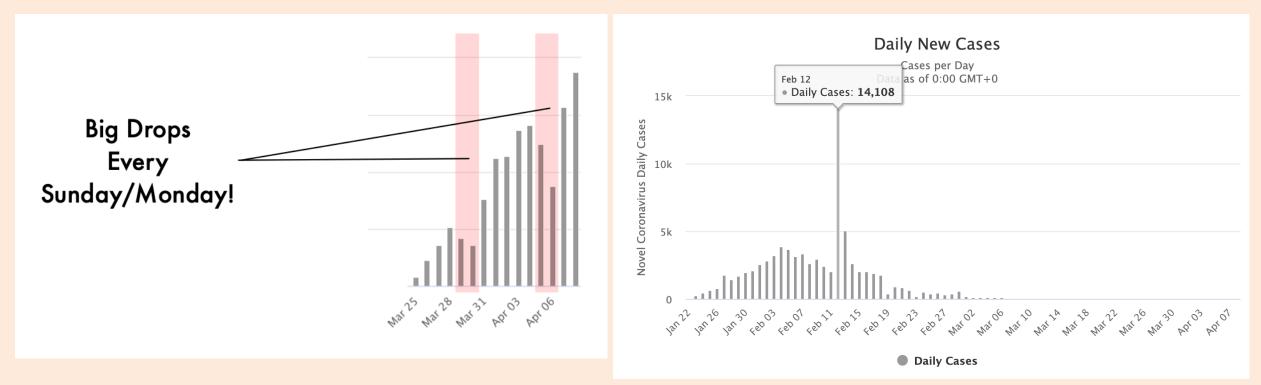

You can do A1 Q5-Q6 now!

Decision Stump Learning Pseudo-Code Input: feature matrix X and label vector y Compute error if using baseline rule: number of times yi does not equal most common value. for each feature j' (column of 'X') for each threshold 't' set 'y-yes to most common label of objects 'i' satisfying rule  $(x_{ij} > t)$ set 'y-no' to most common label of objects not satisfying rule. set 'ŷ' to be our <u>predictions</u> for each object 'i' based on the rule. compute <u>error</u> 'E', number of objects where  $\hat{y}_i \neq y_i$  ( $\hat{y}_i = y_i y_i$  if satisfied,  $\hat{y}_i = y_i$ -no if not satisfied, store the rule  $(j, t, y_i - y_i e_j y_i - no)$  if it has the lowest error so far. Output a "best" decision stump based on score. (the "model")

### • Colors can indicate a third categorical variable.

https://en.wikipedia.org/wiki/lris\_flower\_data\_set http://www.ats.ucla.edu/stat/r/pages/layout.htm

# Scatterplot Arrays

• For multiple variables, can use scatterplot array.

### • Colors can indicate a third categorical variable.

https://en.wikipedia.org/wiki/lris\_flower\_data\_set http://www.ats.ucla.edu/stat/r/pages/layout.htm

# "Why Not to Trust Plots"

- We've seen how summary statistics can be mis-leading.
- Note that plots can also be mis-leading, or can be used to mis-lead.
- Next slide: first example from UW's excellent course:
  - "Calling Bullshit in the Age of Big Data".
    - A course on how to recognize when people are trying to mis-lead you with data.
  - I recommend watching all the videos here:
    - <u>https://www.youtube.com/watch?v=A2OtU5vlR0k&list=PLPnZfvKID1Sje5jWxt-4CSZD7bUI4gSPS</u>
  - Recognizing BS not only useful for data analysis, but for daily life.

# Mis-Leading Axes

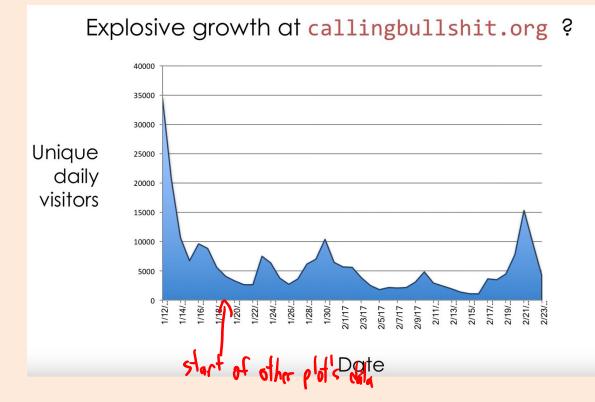

• This plot seems to show amazing recent growth:

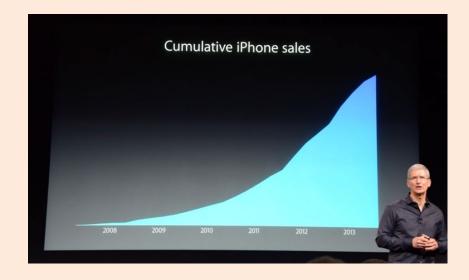

- But notice y-axis starts at 100,000 (so ~40% of growth was earlier).
- And it plots "total" users (which necessarily goes up).

# Mis-Leading Axes

• Plot of actual daily users (starting from 0) looks totally different:

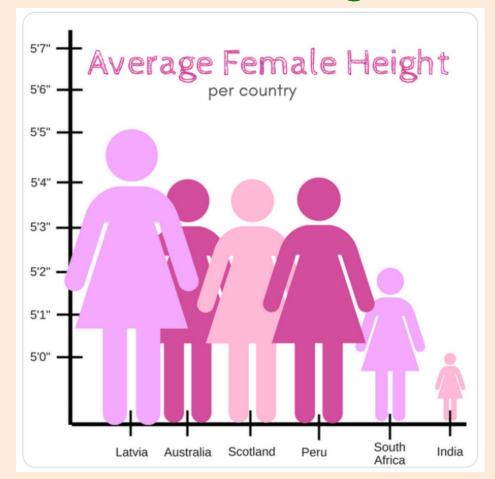

• People can mis-lead to push agendas/stories:

# Mis-Leading Axes

• Watch out for the starting point of the axes too:

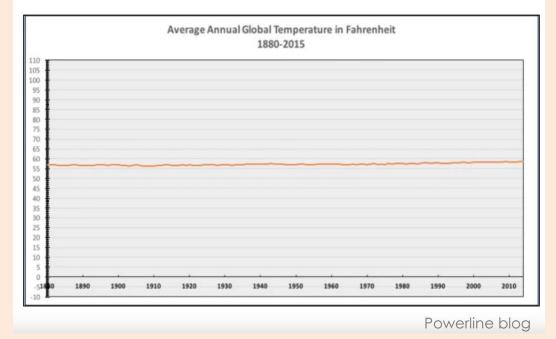

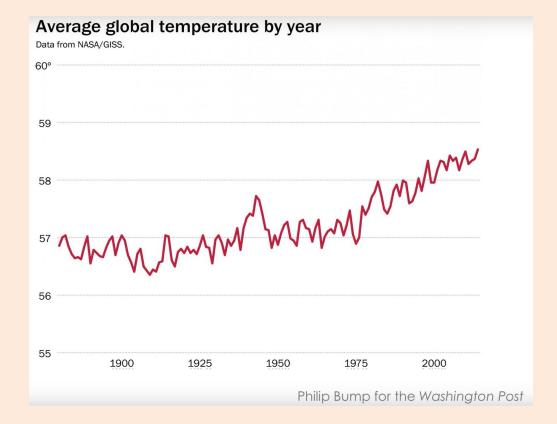

#### https://www.boredpanda.com/average-women-height-data-chart-latvian-

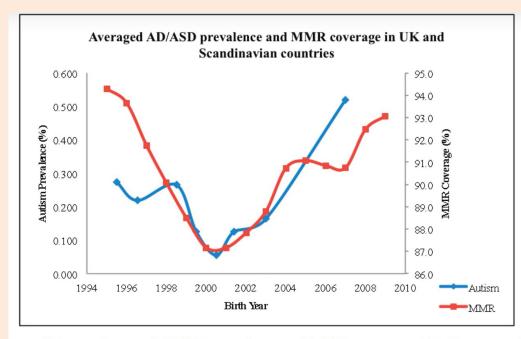

# Mis-Leading Axes

- We see "lack of appropriate axes" ALL THE TIME in the news:
  - "British research revealed that patients taking ibuprofen to treat arthritis face a 24% increased risk of suffering a heart attack"
    - What is probability of heart attack if I you don't take it? Is that big or small?
    - Actual numbers: less than 1 in 1000 "extra" heart attacks vs. baseline frequency.
      - There is a risk, but "24%" is an exaggeration.
    - "Health-scare stories often arise because their authors simply don't understand numbers."
      - Or it could be that they do understand, but media wants to "sensationalize" mundane news.
  - Bonus slides: more "Calling Bullshit" course examples on "political" issues:
    - Global warming, vaccines, gun violence, taxes.

#### "THE ONLY GLOBAL WARMING CHART YOU NEED FROM NOW ON"

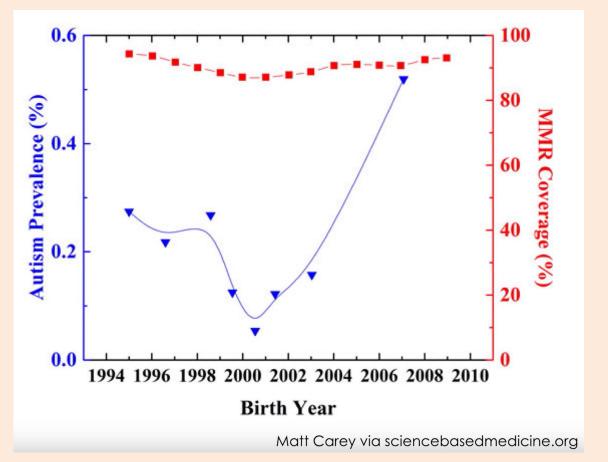

**Figure 1-**Averaged AD/ASD prevalence and MMR coverage in UK, Norway and Sweden. Both MMR and AD/ASD data are normalized to the maximum coverage/prevalence during the time period of this analysis.

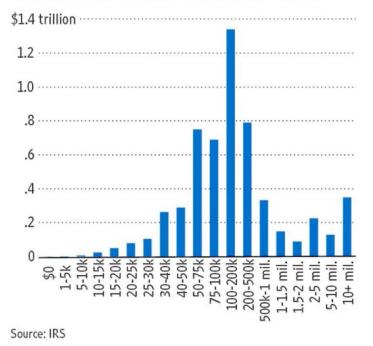

Diesher et al. 2015 Issues in Law and Medicine

#### https://www.youtube.com/watch?v=9pNWVMxaFuM

#### The Middle Class Tax Target

The amount of total taxable income (left scale) for all filers by adjusted gross income level for 2008

"The rich, in short, aren't nearly rich enough to finance Mr. Obama's entitlement state ambitions—even before his healthcare plan kicks in.

So who else is there to tax? Well, in 2008, there was about \$5.65 trillion in total taxable income from all individual taxpayers, and most of that came from middle income earners. The nearby chart shows the distribution, and the big hump in the center is where Democrats are inevitably headed for the same reason that Willie Sutton robbed banks."

> -The Wall Street Journal April 17, 2011

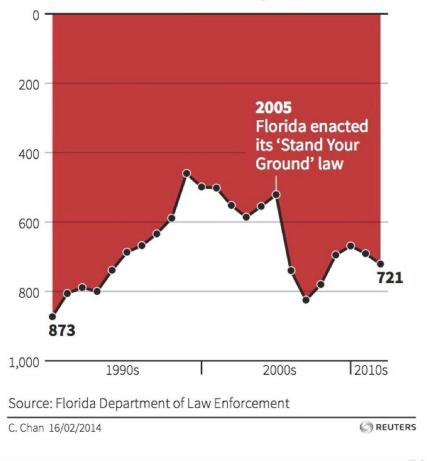

• Look at the histogram bin widths.

https://www.youtube.com/watch?v=zAg1wsYfwsM

- Axis is upside down.
- Looks like law makes murder go down, but number of murders go up!

#### **Gun deaths in Florida**

Number of murders committed using firearms

Via http://blog.heapanalytics.com/how-to-lie-with-data-visualization/

#### https://www.youtube.com/watch?v=9pNWVMxaFuM

• Calling BS gives this as another example:

NBC News 🥏 @NBCNews

International student applications at American schools are down nearly 40 percent, survey shows nbcnews.to/2nTOAIG

2+ Follow

• Actual numbers don't say much of anything:

Key findings of the survey include:

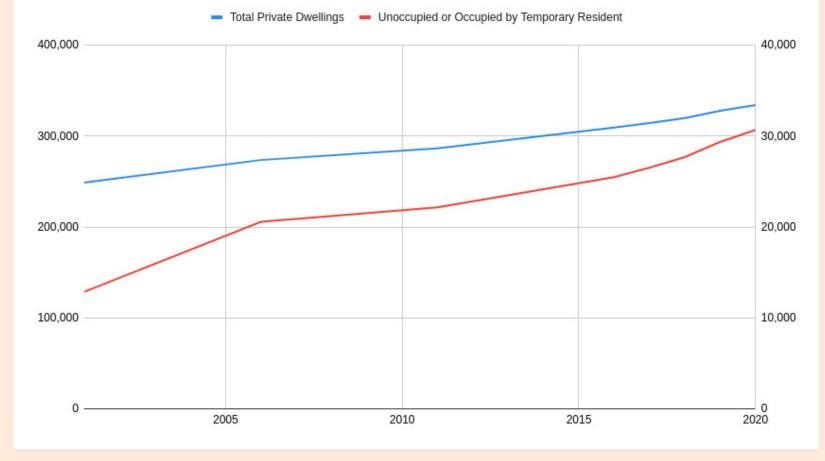

-- 39% of responding institutions reported a decline in international applications, 35% reported an increase, and 26% reported no change in applicant numbers.

- 39% vs. 35% (without sizes) doesn't mean "down nearly 40 percent".
  - Data can be used in mis-leading ways to "push agendas".
  - Even by reputed sources.
  - Even if you agree with the message.

## More Mis-Leading Axes from Vancouver Housing

- A local example:
  - Are almost all
     Vancouver homes
     becoming empty?
  - Or did they use different y-axis scales for each line?

Total Private Dwellings and Unoccupied or Occupied by Temporary Resident

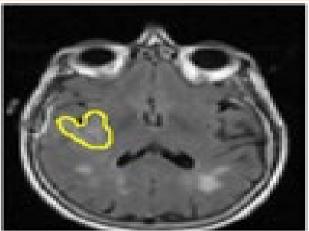

https://openhousing.ca/2020/12/30/vancouver-empty-homes-crossed-

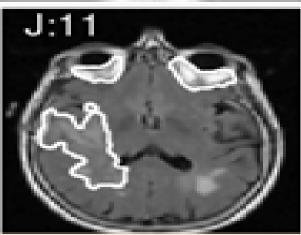

# Hamming Distance vs. Jaccard Coefficient

Α	В
1	0
1	0
1	0
O	1
O	1
1	0
O	0
O	0
O	1

- These vectors agree in 2 positions.
  - Normalizing Hamming distance by vector length, similarity is 2/9.
- If we're really interested in predicting 1s, we could find set of 1s in both and compute Jaccard:
  - A -> {1,2,3,6}, B -> {4,5,9}
  - No intersection so Jaccard similarity is actually 0.

# Hamming Distance vs. Jaccard Coefficient

- Let's say we want to find the tumour in an MR image.
- We have an expert label (top) and a prediction from our ML system (bottom).
- The normalized Hamming distance between the predictions at each pixel is 0.91. This sounds good, but since there are so many non-tumour pixels this is misleading.
- The ML system predicts a much bigger tumour so hasn't done well. The Jaccard coefficient between the two sets of tumour pixels is only 0.11 so reflects this.

# Coupon Collecting

- Consider trying to collect 50 uniformly-distributed states, drawing at random.
- The probability of getting a new state if there 'x' states left: p=x/50.
- So expected number of samples before next "success" (getting a new state) is 50/x.
   (mean of geometric random variable with p=x/50)
- So the expected number of draws is the sum of 50/x for x=1:50.
- For 'n' states instead of 50, summing until you have all 'n' gives:

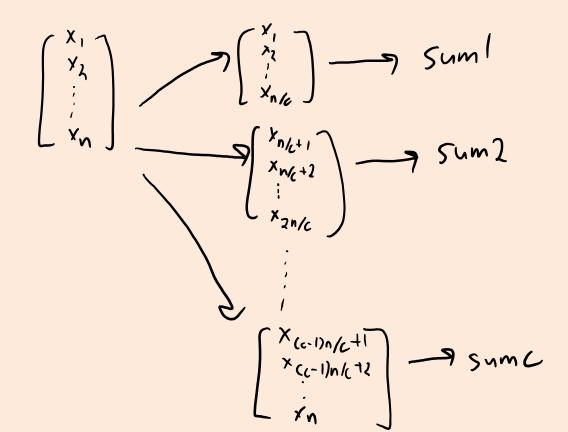

$$\sum_{i=1}^{n} \frac{n}{i} = n \sum_{i=1}^{n} \frac{1}{i} \leq n(1 + \log(n)) = O(n \log n)$$

- Most sufficient statistics can be computed in linear time.
- For example, the mean of 'n' numbers is computed as:

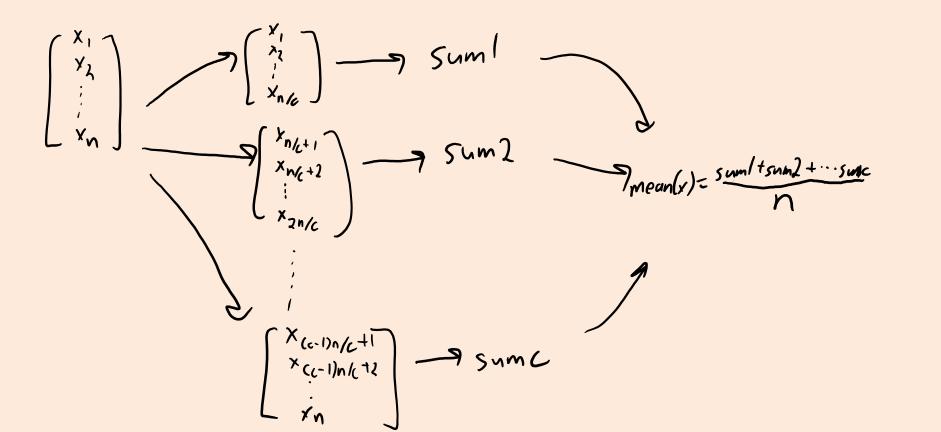

$$mean(x_{1}, x_{2}, x_{3}, \dots, x_{n}) = x_{1} + x_{2} + x_{3} + \dots + x_{n}$$

- This costs O(n), which is great.
- But if 'n' is really big, we can go even faster with parallel computing...

- Computing the mean with multiple cores:
  - Each of the 'c' cores computes the sum of O(n/c) of the data:

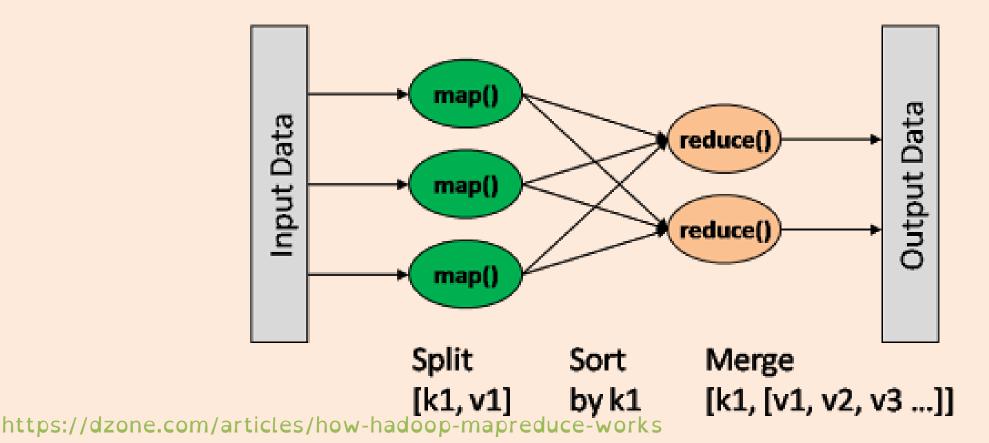

- Computing the mean with multiple cores:
  - Each of the 'c' cores computes the sum of O(n/c) of the data:
  - Add up the 'c' results from each core to get the mean.

- Computing the mean with multiple cores:
  - Each of the 'c' cores computes the sum of O(n/c) of the data.
  - Add up the 'c' results from each core to get the mean.
  - Cost is only O(n/c + c), which can be much faster for large 'n'.
- This assumes cores can access data in parallel (not always true).
- Can reduce cost to O(n/c) by having cores write to same register.
  - But need to "lock" the register and might effectively cost O(n).

- Sometimes 'n' is so big that data can't fit on one computer.
- In this case the data might be distributed across 'c' machines:
   Hopefully, each machine has O(n/c) of the data.
- We can solve the problem similar to the multi-core case:
  - "Map" step: each machine computes the sum of its data.
  - "Reduce" step: each machine communicates sum to a "master" computer, which adds them together and divides by 'n'.

- Many problems in DM and ML have this flavour:
  - "Map" computes an operation on the data on each machine (in parallel).
  - "Reduce" combines the results across machines.

- Many problems in DM and ML have this flavour:
  - "Map" computes an operation on the data on each machine (in parallel).
  - "Reduce" combines the results across machines.
  - These are standard operations in parallel libraries like MPI.
- Can solve many problems almost 'c' times faster with 'c' computers.
- To make it up for the high cost communicating across machines:
  - Assumes that most of the computation is in the "map" step.
  - Often need to assume data is already on the computers at the start.

- Another challenge with "Google-sized" datasets:
  - You may need so many computers to store the data, that it's inevitable that some computers are going to fail.
- Solution to this is a distributed file system.
- Two popular examples are Google's MapReduce and Hadoop DFS:
  - Store data with redundancy (same data is stored in many places).
    - And assume data isn't changing too quickly.
  - Have a strategy for restarting "map" operations on computers that fail.
  - Allows fast calculation of more-fancy things than sufficient statistics:
    - Database queries and matrix multiplications.

## Other Considerations for Food Allergy Example

- What types of preprocessing might we do?
  - Data cleaning: check for and fix missing/unreasonable values.
  - Summary statistics:
    - Can help identify "unclean" data.
    - Correlation might reveal an obvious dependence ("sick" \(Correlation might reveal an obvious dependence ("sick").
  - Data transformations:
    - Convert everything to same scale? (e.g., grams)
    - Add foods from day before? (maybe "sick" depends on multiple days)
    - Add date? (maybe what makes you "sick" changes over time).
  - Data visualization: look at a scatterplot of each feature and the label.
    - Maybe the visualization will show something weird in the features.
    - Maybe the pattern is really obvious!
- What you do might depend on how much data you have:
  - Very little data:
    - Represent food by common allergic ingredients (lactose, gluten, etc.)?
  - Lots of data:
    - Use more fine-grained features (bread from bakery vs. hamburger bun)?

### Julia Decision Stump Code (not O(n log n) yet)

Input: feature matrix X and label vector y  
(n,d) = size(X)  
minError = sum(y |= mode(y)) compute error if you don't split (user-defined function 'mode'  
minRule = []  
for j = 1:d for each feature 'j'  
for j = 1:n for each feature 'j'  

$$f = X[i,j]$$
 set threshold to feature 'j' in example 'i'  
y above = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is above threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = mode(y[X[:,j],>t]) find mode of label vector when feature 'j' is below threshold  
y below = fill(y-above, n) classify all examples based on threshold  
y hat [X[:,j], = t] = y-below  
error = sum(y hat != y) count the number of errors.  
if error < min Error  
minFire = Error  
minFire = Error to time the time if it has the lowest error so far.  
minFire = Error to time the time to the ti

### Going from O(n<sup>2</sup>d) to O(nd log n) for Numerical Features

- Do we have to compute score from scratch?
  - As an example, assume we eat integer number of eggs:
    - So the rules (egg > 1) and (egg > 2) have same decisions, except when (egg == 2).
- We can actually compute the best rule involving 'egg' in O(n log n):
  - Sort the examples based on 'egg', and use these positions to re-arrange 'y'.
  - Go through the sorted values in order, updating the counts of #sick and #not-sick that both satisfy and don't satisfy the rules.
  - With these counts, it's easy to compute the classification accuracy (see bonus slide).
- Sorting costs O(n log n) per feature.
- Total cost of updating counts is O(n) per feature.
- Total cost is reduced from O(n<sup>2</sup>d) to O(nd log n).
- This is a good runtime:
  - O(nd) is the size of data, same as runtime up to a log factor.
  - We can apply this algorithm to huge datasets.

# How do we fit stumps in O(nd log n)?

• Let's say we're trying to find the best rule involving milk:

Eg	Mil	••••	Sick?
g	k		1
0	0.7		1
1	0.7		0
0	0		1
1	0.6		0
1	0		1
2	0.6		1
0	1		1
2	0		0
0	0.3		0
1	0.6		1
2	0		

First grab the milk column and sort it (using the sort positions to re-arrange)	Mil k	Si	C
the sick column). This step costs O(n log n) due to sorting.	× 0		( (
Now, we'll go through the milk values	0		C
in order, keeping track of #sick and	0		Ċ
<pre>#not sick that are above/below the current value. E.g., #sick above 0.3 is</pre>	0 0.3		0
5.	0.6		]
With these counts, accuracy score is	0.6		(
(sum of most common label above and below)/n.	0.6		1
	0.7 0.7		1
	1		1

# How do we fit stumps in O(nd log n)?

Start with the baseline rule () which is always "satisfied".

Mil k	
0	
0	
0	
0	
0.3	
0.6	
0.6	
0.6	
0.7	
0.7	
1	

	Start with the baseline rule () which is always "satisfied :
Sick?	If satisfied, #sick=5 and #not-sick=6.
0	If not satisfied, #sick=0 and #not-sick=0.
Ο	This gives accuracy of $(6+0)/n = 6/11$ .
Ŭ	
0	Next try the rule (milk $> 0$ ), and update the counts based on these 4 rows:
0	If satisfied, #sick=5 and #not-sick=2.
0	If not satisfied, #sick=0 and #not-sick=4.
0	This gives accuracy of $(5+4)/n = 9/11$ , which is better.
1	
1	Next try the rule (milk $> 0.3$ ), and update the counts based on this 1 row:
	If satisfied, #sick=5 and #not-sick=1.
0	If not satisfied, #sick=0 and #not-sick=5.
1	This gives accuracy of $(5+5)/n = 10/11$ , which is better.
1	(and keep going until you get to the end)
1	

# How do we fit stumps in O(nd log n)?

Mil	Sick?
k	0
0	Ο
0	0
0	0
0	0
0.3	1
0.6	1
0.6	0
0.6	1
0.7	1
0.7	1
1	

Notice that for each row, updating the counts only costs O(1). Since there are O(n) rows, total cost of updating counts is O(n).

Instead of 2 labels (sick vs. not-sick), consider the case of 'k' labels:

- Updating the counts still costs O(n), since each row has one label.
- But computing the 'max' across the labels costs O(k), so cost is O(kn).

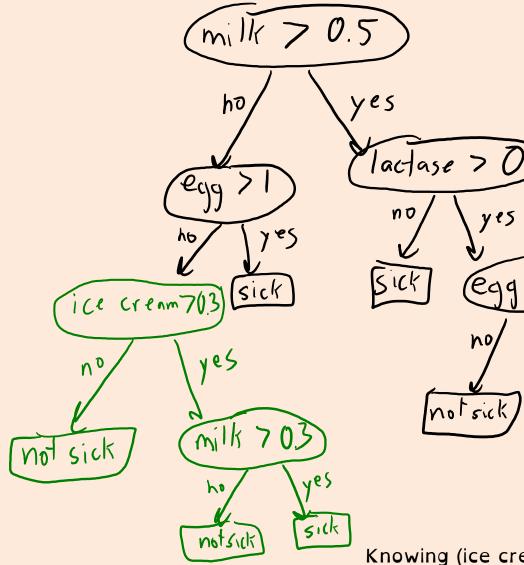

With 'k' labels, you can decrease cost using a "max-heap" data structure:

- Cost of getting max is O(1), cost of updating heap for a row is O(log k).
- But  $k \leq n$  (each row has only one label).
- So cost is in O(log n) for one row.

Since the above shows we can find best rule in one column in O(n log n), total cost to find best rule across all 'd' columns is O(nd log n).

# Can decision trees re-visit a feature?

• Yes.

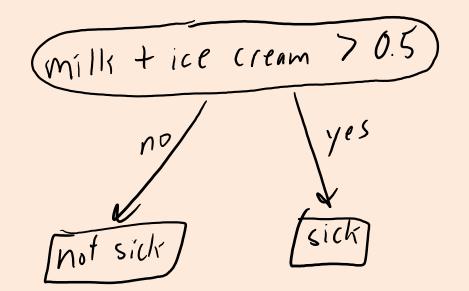

Knowing (ice cream > 0.3) makes small milk quantities relevan

y-es

Sick /

### Can decision trees have more complicated rules?

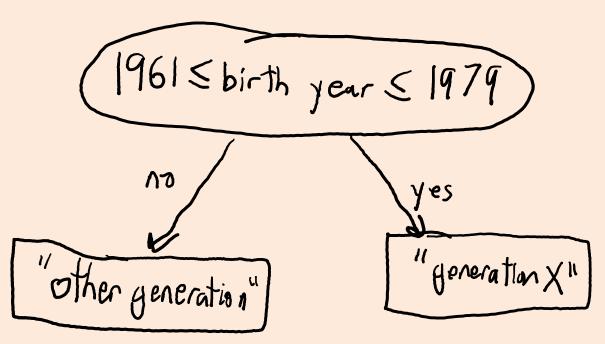

- Yes!
- Rules that depend on more than one feature:

• But now searching for the best rule can get expensive.

### Can decision trees have more complicated rules?

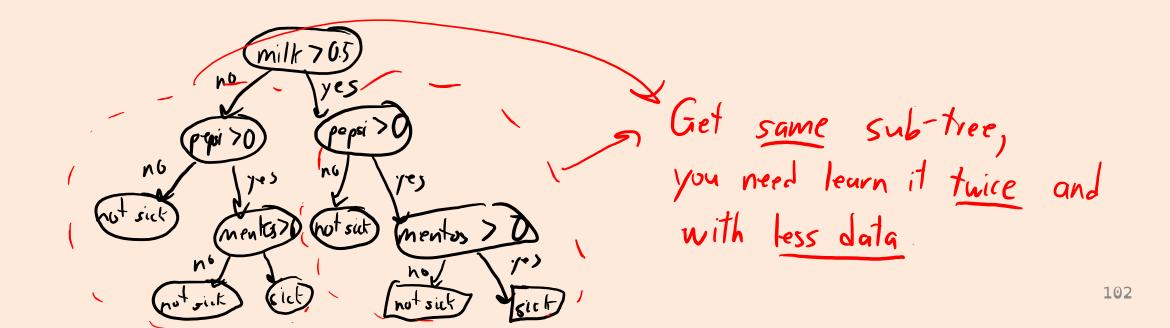

- Yes!
- Rules that depend on more than one threshold:

- "Very Simple Classification Rules Perform Well on Most Commonly Used Datasets"
  - Consider decision stumps based on multiple splits of 1 attribute.
  - Showed that this gives comparable performance to more-fancy methods on many datasets.

# Does being greedy actually hurt?

- Can't you just go deeper to correct greedy decisions?
  - Yes, but you need to "re-discover" rules with less data.
- Consider that you are allergic to milk (and drink this often), and also get sick when you (rarely) combine diet coke with mentos.
- Greedy method should first split on milk (helps accuracy the most):

# Does being greedy actually hurt?

- Can't you just go deeper to correct greedy decisions?
  - Yes, but you need to "re-discover" rules with less data.
- Consider that you are allergic to milk (and drink this often), and also get sick when you (rarely) combine diet coke with mentos.
- Greedy method should first split on milk (helps accuracy the most).
- Non-greedy method could get simpler tree (split on milk later):

# **Decision Trees with Probabilistic Predictions**

- Often, we'll have multiple 'y' values at each leaf node.
- In these cases, we might return probabilities instead of a label.
- E.g., if in the leaf node we 5 have "sick" examples and 1 "not sick":
   Return p(y = "sick" | x<sub>i</sub>) = 5/6 and p(y = "not sick" | x<sub>i</sub>) = 1/6.
- In general, a natural estimate of the probabilities at the leaf nodes:
  - Let ' $n_k$ ' be the number of examples that arrive to leaf node 'k'.
  - Let ' $n_{kc}$ ' be the number of times (y == c) in the examples at leaf node 'k'.
  - Maximum likelihood estimate for this leaf is  $p(y = c | x_i) = n_{kc}/n_k$ .

# Alternative Stopping Rules

- There are more complicated rules for deciding when \*not\* to split.
- Rules based on minimum sample size.
  - Don't split any nodes where the number of examples is less than some 'm'.
  - Don't split any nodes that create children with less than 'm' examples.
    - These types of rules try to make sure that you have enough data to justify decisions.
- Alternately, you can use a validation set (see next lecture):
  - Don't split the node if it decreases an approximation of test accuracy.
